

Differential and shared genetic effects on kidney function between diabetic and non-diabetic individuals

Reduced glomerular filtration rate (GFR) can progress to kidney failure. Risk factors include genetics and diabetes mellitus (DM), but little is known about their interaction. We conducted genome-wide association meta-analyses for estimated GFR based on serum creatinine (eGFR), separately for individuals with or without DM ($n_{DM} = 178,691$, $n_{noDM} = 1,296,113$). Our genome-wide searches identified (i) seven eGFR loci with significant DM/noDM-difference, (ii) four additional novel loci with suggestive difference and (iii) 28 further novel loci (including *CUBN*) by allowing for potential difference. GWAS on eGFR among DM individuals identified 2 known and 27 potentially responsible loci for diabetic kidney disease. Gene prioritization highlighted 18 genes that may inform reno-protective drug development. We highlight the existence of DM-only and noDM-only effects, which can inform about the target group, if respective genes are advanced as drug targets. Largely shared effects suggest that most drug interventions to alter eGFR should be effective in DM and noDM.

Impaired kidney function can progress to kidney failure requiring dialysis or transplantation, which implicates high early mortality¹ and public health burden². The most common kidney function measure is the glomerular filtration rate (GFR). Chronic kidney disease (CKD) can be defined as GFR < 60 ml/min per 1.73 m², and has a prevalence of ~10% in the population³. In large-scale epidemiological studies, GFR can be estimated from serum creatinine (eGFR) using the CKD-Epi formula⁴.

Diabetes mellitus (DM) is a major risk factor for impaired kidney function⁵ and is present in 30% of individuals starting dialysis in Europe⁶. Most current pharmacotherapy in DM has substantial side effects^{7–10}. Recent work showed that SGLT2 inhibitors and GLP1R are reno-protective for individuals with DM^{11,12} and early evidence indicates that this might be also true for individuals without DM (noDM)¹³. The biological processes related to lower kidney function might differ between individuals with DM and individuals without DM. Understanding the mechanisms of kidney function variability within and between these groups is pivotal for understanding pathogenesis. Genome-wide association studies (GWAS) have pinpointed hundreds of loci for eGFR^{14–16}. These loci help understand kidney function variability in the overall population. However, commonalities and differences in genetic kidney function effects between DM and noDM individuals are not well understood.

Genes underneath GWAS loci have been shown to double the success rate in drug development pipelines^{17,18}. This renders each gene in eGFR loci a drug target to alter kidney function, particularly when the gene maps to association-driving variants that are relevant for the protein or for the gene's expression in kidney tissue¹⁹. This opens up a clinically important question in the context of differential or shared genetic kidney function effects between DM and noDM individuals: when a locus identified for eGFR in the overall population turns out to have no effect in DM individuals, the underlying causal gene might not be informative for reno-protection in DM individuals. This is not an unlikely scenario, since only 10% of individuals in previous population-based GWAS on eGFR overall had DM^{16,20}.

Previous DM-/noDM-stratified searches for genetic eGFR-effects have been limited²¹ and without identification of a significant DM/noDM-difference. It is unclear whether this was due to limited power or lack of such differential effects. GWAS for eGFR-based kidney function outcomes in DM, used as one approach to identify the genetics of Diabetic Kidney Disease (DKD), identified four loci in ~40,000 type 1 or type 2 DM patients²² and four other loci in ~19,500 type 1 DM patients²³. When genetic effects on eGFR in DM versus noDM have little overlap, such focused searches will remain the best option. For shared genetics, GWAS on eGFR overall will have much better power.

The quest for understanding commonalities and differences of genetic eGFR-effects between DM and noDM has two aspects: a search for eGFR-associated loci with DM/noDM-difference will help understand whether such differential effects exist and a search for SNP-association on eGFR allowing for DM/noDM-difference may detect novel eGFR loci. Statistically, DM/noDM-difference in eGFR association and genetics-by-DM-status interaction on eGFR association are equivalent. There are various approaches to do so²⁴. These approaches have been applied successfully for other phenotypes^{25–29}, but not yet for GWAS interaction analyses for kidney function.

We thus set out to search for eGFR loci with DM/noDM-difference and for novel eGFR loci allowing for difference. For this, we gathered GWAS data on eGFR separately for 178,691 DM and 1,296,113 noDM individuals. We prioritized genes underneath identified loci using in-silico functional evidence. We also

evaluated the impact of DM-/noDM-specific weights on the genetic risk score (GRS) for eGFR in data independent from the variant- and weight-identifying step³⁰.

Results

Overview of the GWAS meta-analyses. We first analyzed GWAS data on 7,046,926 single nucleotide polymorphisms (SNPs) and their association with logarithm-transformed eGFR separately for 109,993 DM (type 2 or type 1) and 1,070,999 noDM individuals (stage 1, including 72 studies from CKDGen Consortium³¹ and UK Biobank, UKB³²; mostly European-ancestry; Supplementary Data 1, Methods, Fig. 1a). These DM-/noDM-stratified GWAS summary statistics allowed us to apply the difference test, the joint test and the stratified tests (Methods). Based on these tests, we searched for eGFR-associated loci with DM/noDM-difference and for novel eGFR-associated loci allowing for DM/noDM-difference.

We sought replication of identified loci in independent DM-/noDM-stratified data (stage 2, $n_{DM} = 68,698$, $n_{noDM} = 225,114$; Million Veterans Program, MVP³³; Michigan Genomics Initiative, MGI³⁴; Trøndelag health study, HUNT³⁵; all European-ancestry; Supplementary Data 1, Methods). While the discovery+replication design augments confidence in identified loci, this comes at the cost of lower power³⁶. We also conducted GWAS searches in a combined stage design (stage 1 + 2: $n_{DM} = 178,691$, $n_{noDM} = 1,296,113$), to yield significant loci exploiting the full sample size, yet without independent replication.

The two stages of data were also used to separate the variant identification and weight quantification for the GRS (stage 1 data) from the GRS association analyses (stage 2 data). The analysis workflow is shown in Fig. 1.

Seven eGFR loci identified with DM-/noDM-differential effects. To search for eGFR loci with DM/noDM-difference, we applied two approaches^{24,37} (Fig. 1b): (i) a genome-wide difference test ($P_{Diff} < 5 \times 10^{-8}$, difference test approach), and (ii) a search for genome-wide significant association with overall eGFR followed by a difference test in the same data ($P_{Overall} < 5 \times 10^{-8}$ and $P_{Diff} < 0.05/k$, $k = \text{number of followed SNPs}$, overall+difference test approach, Methods).

In the discovery search (stage 1, $n_{DM} = 109,993$; $n_{noDM} = 1,070,999$), we identified four eGFR loci with significant DM/noDM-difference (Supplementary Fig. 1): (i) two by the difference test approach (rs77924615 near *UMOD-PDILT*, rs12233328 near *PDE9A*; $P_{Diff} < 5 \times 10^{-8}$, Supplementary Data 2), and (ii) two further loci by the overall+difference test approach (near *TPPP* and *MED1-NEUROD2*; $P_{Overall} < 5 \times 10^{-8}$ and $P_{Diff} < 0.05/610 = 8.2 \times 10^{-5}$; corrected for 610 followed variants¹⁶, Supplementary Data 2). Details of the overall +difference test results are provided in Supplementary Note 1 and Supplementary Data 3, conditional difference analyses on known $P_{Overall} < 5 \times 10^{-8}$ variants in *UMOD-PDILT* in Supplementary Fig. 2. In stage 2 data ($n_{DM} = 68,698$, $n_{noDM} = 225,114$), three of the four loci replicated (near *UMOD-PDILT*, *MED1-NEUROD2*, and *TPPP*; one-sided $P_{Diff} < 0.05/4 = 0.0125$; Table 1, Supplementary Data 2), while the *PDE9A* locus variant did not ($P_{Diff} = 0.30$).

In the combined stage design (stage 1 + 2: $n_{DM} = 178,691$; $n_{noDM} = 1,296,113$), we identified seven eGFR loci with significant DM/noDM-difference (Table 1, Fig. 2a, Supplementary Fig. 3): (i) six loci by the difference test approach ($P_{Diff} < 5 \times 10^{-8}$, Supplementary Data 2) including the three loci already found by the discovery+replication approach now all with $P_{Diff} < 5 \times 10^{-8}$ (near *UMOD-PDILT*, *TPPP*, and *MED1-NEUROD2*), and three additional loci (near *CSRNP*, *DCDC5*, and *NRIP1*), (ii) one locus

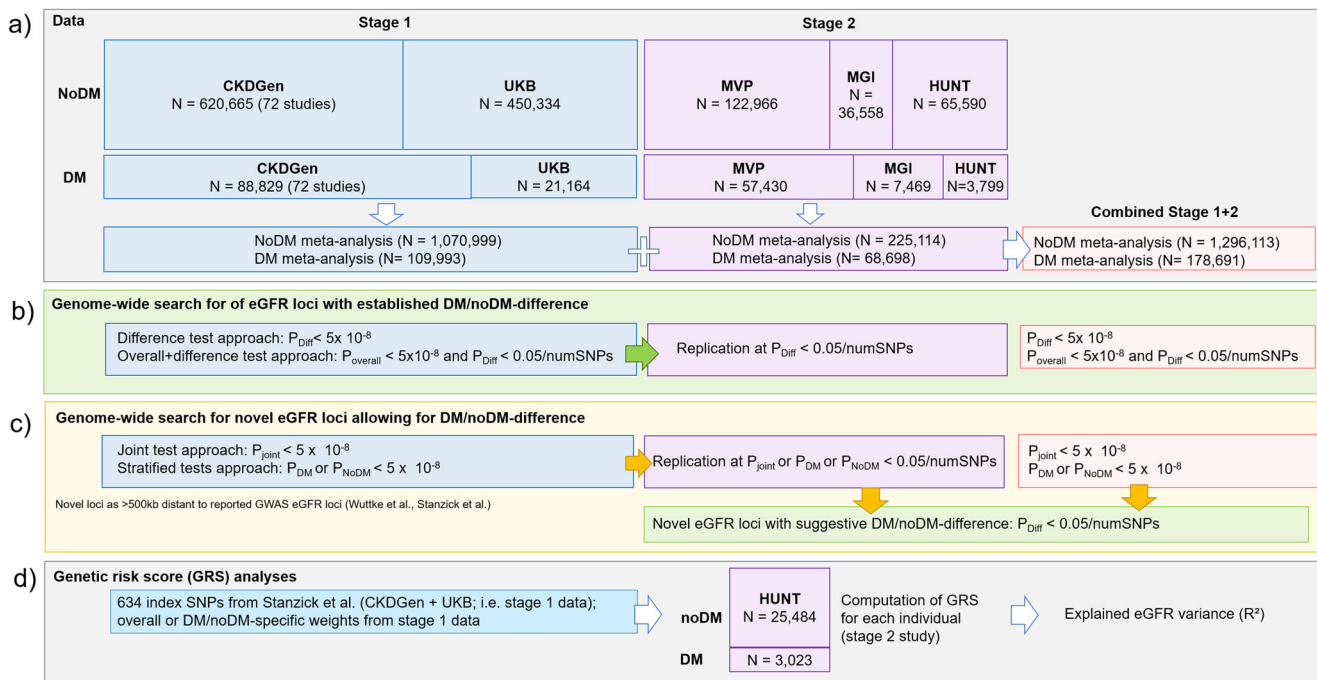

Fig. 1 Data and analysis workflow. a Overview on datasets and meta-analyses. **b** Approaches to identify DM/noDM-differences. **c** Approaches to identify novel eGFR loci and suggestive DM/noDM-differences. **d** Genetic risk score (GRS) analyses in HUNT.

from the overall+difference test approach (near *SLC22A2*; $P_{\text{Overall}} < 5 \times 10^{-8}$ and $P_{\text{Diff}} < 0.05/610 = 8.2 \times 10^{-5}$; 610 followed variants as described above, Supplementary Data 2).

Approximate conditional analyses using the difference test (combined stage 1 + 2, European only, Methods) did not identify any further independent variants within the 7 identified difference loci (regional difference plots in Supplementary Fig. 4). Interestingly, there was also no further independent variant with DM/noDM-difference in the *UMOD-PDILT* locus besides rs77924715, despite the multiple independent variants known for eGFR association overall^{16,20} (Supplementary Fig. 4a, b). Sensitivity analyses confirmed that DM/noDM-difference was also observed without log-transformation of eGFR and also after adjusting for interaction with age or other eGFR risk factors (Supplementary Note 2, Supplementary Data 4, Supplementary Table 1).

With respect to DM-/noDM specificity and magnitude of effects, we found the following (Fig. 2b): (i) six of the seven variants identified with differential eGFR-effects showed more pronounced effects in DM versus noDM (near *UMOD-PDILT*, *TPPP*, *DCDC5*, *NRIP1*, and *SLC22A2*) or a DM-only effect on eGFR (near *CSRNPI*) and (ii) one variant showed a noDM-only effect (near *MED1-NEUROD2*). These patterns were consistent in stage 1 and stage 2 separately (Supplementary Fig. 5). Of note, with the combined stage 1 + 2 sample size, the difference detectable for a common variant of 30% minor allele frequency at 80% power was 0.0050 or 0.0037 $\log(\text{ml}/\text{min}/1.73 \text{ m}^2)$ for a DM-only or noDM-only effect, respectively (Supplementary Note 3, Supplementary Fig. 6).

In summary, we established seven eGFR loci with DM/noDM-difference (near *UMOD-PDILT*, *TPPP*, *MED1-NEUROD2*, *CSRNPI*, *DCDC5*, *NRIP1*, and *SLC22A2*) including one with DM-only (*CSRNPI*) and one with noDM-only effect (*MED1-NEUROD2*). While all seven difference loci were known loci for eGFR¹⁶, these are the first eGFR loci reported with significant DM/noDM-difference from a genome-wide search for the difference to the best of our knowledge.

Allowing for difference identifies 32 novel eGFR-associated loci including *CUBN*. To search for novel eGFR-associated loci allowing for the difference between DM and noDM, we applied two approaches (Fig. 1c, Methods): (i) a genome-wide joint test³⁸, which considers the main SNP effect on eGFR and the SNP-by-DM-status interaction effect jointly (joint-test approach) and (ii) GWAS separately in DM or noDM (stratified tests approach).

In the discovery (stage 1; $n_{\text{DM}} = 109,993$, $n_{\text{noDM}} = 1,070,999$), we identified 25 novel eGFR loci after excluding previously identified GWAS eGFR loci^{16,20} ($P_{\text{Joint}} \text{ or } P_{\text{noDM}} < 5 \times 10^{-8}$, none by $P_{\text{DM}} < 5 \times 10^{-8}$, Supplementary Data 5, Supplementary Fig. 7a). In stage 2 data ($n_{\text{DM}} = 68,698$, $n_{\text{noDM}} = 225,114$), three of the 25 loci replicated ($P_{\text{Joint}} \text{ or } P_{\text{noDM}} < 0.05/25$; near *ATP12A*, *SERTAD2*, and *ABCC2*, Table 2).

In the combined stage design (stage 1 + 2: $n_{\text{DM}} = 178,691$, $n_{\text{noDM}} = 1,296,113$), we identified 32 novel eGFR loci ($P_{\text{Joint}} \text{ or } P_{\text{DM}} \text{ or } P_{\text{noDM}} < 5 \times 10^{-8}$, Fig. 3a, Table 2, Supplementary Data 5, Supplementary Fig. 7b): (i) 30 novel loci by the joint test; (ii) two additional loci by the noDM-only search (near *FAT4*, *SLC2A4*). While no locus was additionally identified by the DM-only search, two of the 32 novel loci were genome-wide significant in DM ($P_{\text{DM}} < 5 \times 10^{-8}$; near *SH3BP4*, *LOXL4*; also identified by joint test).

These 32 novel loci included the three replicated novel loci from the discovery+replication approach (near *ATP12A*, *SERTAD2*, and *ABCC2*) (Table 2). The 29 additional novel loci included the *CUBN* locus, which is well-known for urinary albumin-to-creatinine ratio (UACR)³⁹ and microalbuminuria⁴⁰ (Fig. 4). The identified *CUBN* locus eGFR lead variant, rs11254238, showed (i) no correlation with the known signals for UACR ($r^2 < 0.001$, $D' > 0.24$ to any of the known independent signal variants for UACR, rs141493439, rs45551835, rs557338857, rs562661763, rs74375025), (ii) no effect on UACR⁴¹ ($P = 0.57$, Supplementary Data 6), and (iii) a twice as large effect on eGFR in DM compared to noDM, but the difference was not significant ($b_{\text{DM}} = 0.0048$, $b_{\text{noDM}} = 0.0021$, $P_{\text{Diff}} = 0.07$).

Table 1 Search for difference loci identified seven eGFR loci with established difference between DM and noDM.

Shown are seven locus lead variants established with significant difference by two designs and two approaches using stage 1 (CKDGen and UKB, $n_{DM} = 109,993$, $n_{noDM} = 1,070,999$), stage 2 (MVP, MGI, and HUNT, $n_{DM} = 68,698$; $n_{noDM} = 225,114$), and combined data ($n_{DM} = 178,691$, $n_{noDM} = 1,296,113$). (i) Discovery+replication design: three variants discovered in stage 1 data were replicated in stage 2, including one by difference test approach (stage 1 $P_{Diff} < 5 \times 10^{-6}$ and stage 2 one-sided $P_{Diff} < 0.0125 = 0.05/4$, corrected for four variants discovered at stage 1) and two further variants by the overall+difference test approach (610 variants¹⁶ with $P_{Overall} < 5 \times 10^{-8}$, stage 1 $P_{Diff} < 0.05/610$ and stage 2 one-sided $P_{Diff} < 0.05/4$). (ii) Combined stage design: four additional variants were identified in the combined stage design, including three by the difference test approach ($P_{Diff} < 5 \times 10^{-8}$) and one further by the overall+difference test approach (610 variants¹⁶ with $P_{Overall} < 5 \times 10^{-8}$, stage 1 + 2 $P_{Diff} < 0.05/610$). Identifying P-values are stated in bold. Full summary statistics by DM status and stages are shown in Supplementary Data 2.

DM diabetes mellitus, Chr chromosome, Pos position (GRCh37), ea effect allele, eaf effect allele frequency in DM, Stage 1, beta Genetic effect estimates on log eGFR per allele, p Association P-value, P_{Diff} Difference P-value.

Approximate conditional analyses (combined stage, European only, Methods) identified two additional variants independently associated with eGFR at two joint-test loci (near *SERTAD2* and *PIK3CG*, $P_{Joint_cond} < 5 \times 10^{-8}$, Supplementary Table 2). This raised the total number of newly identified eGFR-associated variants to 34.

Among the 34 novel eGFR variants, four showed a suggestive DM/noDM-difference for eGFR ($P_{Diff} < 0.0015 = 0.05/34$, Table 2, Fig. 3b): one was a DM-only effect (near *SH3BP4*) and three showed more pronounced effects in DM (near *LOXL4*, *ALPL*, and *PIK3CG*). These patterns were consistent also in stage 1 and stage 2 separately (Supplementary Fig. 5). Of note, the difference test is mathematically dependent on the joint test and the stratified tests, but not on the overall test²⁴. Therefore, the observed difference in the overall+difference test approach applied to the same data is an established significant difference, while the observed difference in loci established by the joint or stratified tests is termed here as suggestive difference.

In summary, the joint test and stratified tests identified 34 genome-wide significant independent eGFR variants across 32 novel eGFR loci. These included four loci with suggestive DM/noDM-difference, which yielded a total of 11 eGFR loci with established or suggestive DM/noDM-difference.

Interaction with Hba1C and overlap with associations for DM risk, glycemic and other traits. We explored the lead variants of the 11 eGFR loci identified with DM/noDM-difference (i.e., established/suggestive SNP-by-DM interaction) for SNP-by-HbA1c interaction in UK Biobank ($n = 368,005$), making full use of the continuous variable HbA1c instead of binary DM status. For all 11 variants, the SNP main effects and SNP-by-HbA1c interaction effect sizes were directionally consistent with main and interaction effects sizes in the SNP-by-DM interaction analysis (Supplementary Data 7, Methods). This underscored again the negative interaction effect for the 10 of the 11 variants with larger effects in DM or DM-only effects, while the one variant (near *MEDI/NEUROD2*) showed a negative interaction effect for the SNP-by-DM as well as the SNP-by-HbA1c interaction.

We were also interested in whether any of the 11 loci with DM/noDM-difference overlapped with known genome-wide significant loci for type 1 DM⁴², type 2 DM¹⁹, or glycemic traits⁴³. None of the 11 loci overlapped with type 1 DM, type 2 DM, or glycemic traits loci (all 11 lead variants $P > 5.0 \times 10^{-8}$ in published GWAS for DM risk, glucose, or insulin levels, Supplementary Data 8). None of the 11 variants was associated with type 1 DM judged at Bonferroni-corrected significance ($P > 0.05/11 = 4.5 \times 10^{-3}$). Three of the 11 variants were associated with type 2 DM ($P < 0.05/11 = 4.5 \times 10^{-3}$, rs77924615 near *UMOD-PDILT*, rs55722796 near *MEDI-NEUROD2*) or fasting glucose (rs963837 near *DCDC5*). For all three variants, the eGFR-lowering allele was associated with decreased type 2 DM risk or fasting glucose. Thus, the SNP effect on eGFR cannot be fully explained by DM status, which would have yielded a DM risk increasing or glucose-increasing effect by the eGFR-lowering allele. The observation is in line with a pleiotropic effect on DM and eGFR, but with adverse effects for one of the two (eGFR or DM/glucose) and a beneficial effect for the other, which should be considered in drug design when applicable. When taking into account the DM/noDM-stratum where the eGFR effect was more pronounced, the three variants consisted of (i) two variants with stronger eGFR-effects in DM (still significant eGFR effect in noDM, near *UMOD/PDILT* and *DCDC5*) and (ii) one variant with a noDM-only effect on eGFR (near *MEDI-NEUROD2*).

We also queried the Open Targets Genetics database⁴⁴ for associations of the 11 variants with other traits. We found 126

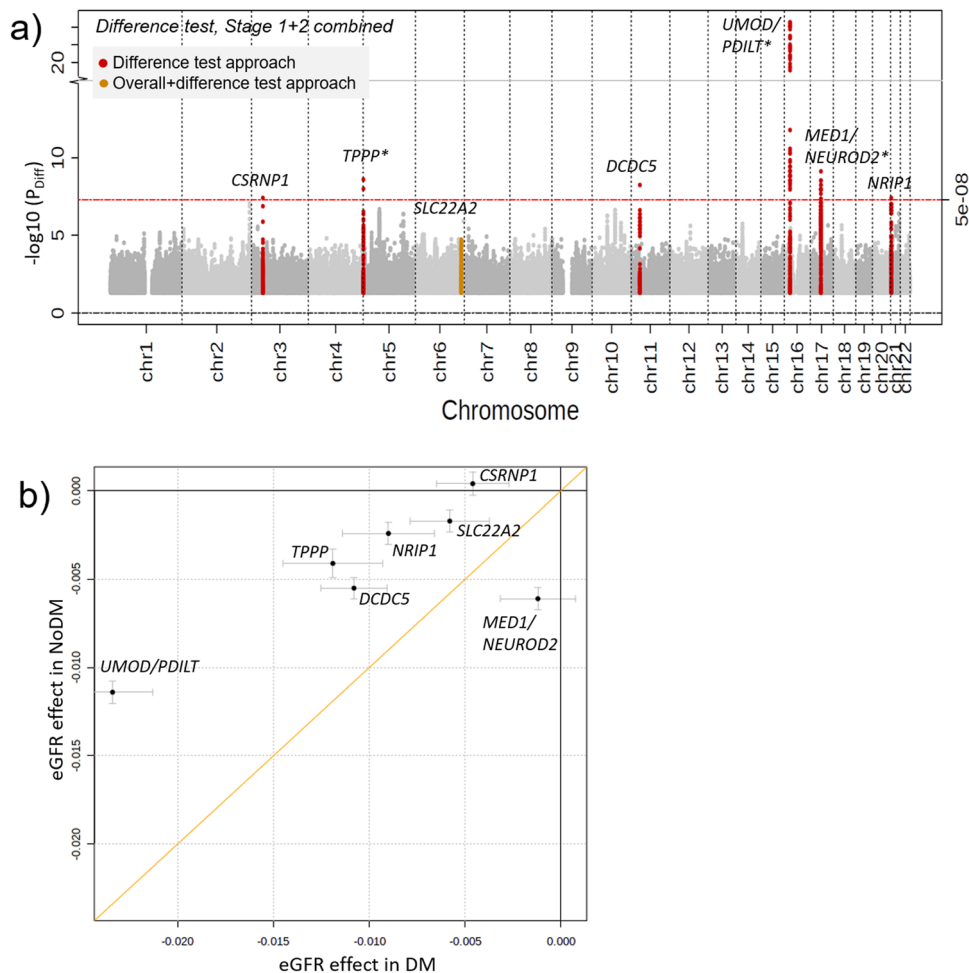

Fig. 2 Seven eGFR loci with differential effects by diabetes status. We searched for DM/noDM-differential genetic associations on eGFR using the difference test approach and the overall+difference approach in combined stage 1 + 2 (CKDGen, UKB, MVP, MGI, and HUNT; $n_{DM} = 178,691$; total $n_{noDM} = 1,296,113$). Seven difference loci were identified. **a** Shown are difference test P -values over chromosomal base position (Manhattan plot) highlighting the six loci identified by the difference test approach (red, $P_{Diff} < 5 \times 10^{-8}$) and the one locus identified by the overall+difference test approach (orange, 610 variants¹⁶ with stage 1 $P_{Overall} < 5 \times 10^{-8}$, $P_{Diff} < 0.05/610 = 8.2 \times 10^{-5}$). Loci are annotated by the name(s) of the nearest gene(s); asterisk indicates loci that were also identified by the discovery+replication design (Table 1, Supplementary Fig. 1). **b** Shown is a comparison of DM-/noDM-specific eGFR-effect sizes for the seven identified difference lead variants based on combined stage 1 + 2 data. Effect sizes are aligned to the eGFR-decreasing alleles in noDM except for *CSRNP1* (aligned to eGFR-decreasing allele in DM). Error bars reflect 95% confidence intervals of the estimated genetic effect.

genome-wide significant associations ($P < 5 \times 10^{-8}$, Supplementary Data 9), particularly for hypertension and blood counts: for 3 of the 11 variants, the eGFR-decreasing alleles were associated with increased risk of hypertension (near *UMOD/PDILT*, *DCDC5*, and *PIK3CG*). The variant rs55722796 near *MED1/NEUROD2*, solely associated with eGFR in noDM individuals, was not associated with hypertension, but the eGFR-decreasing allele (in noDM) was associated with decreased blood counts (i.e., decreased red blood cells, hemoglobin, and hematocrit).

GWAS for eGFR in individuals with DM identified 29 genome-wide significant loci. Previous searches for SNP-effects on eGFR-based kidney function outcome in DM patients had identified eight genome-wide significant loci (i.e., eGFR-based DKD loci; four identified in type 1 DM patients²³, four other in type 1 or type 2 DM patients²²). We wanted to understand the overlap of these with the genome-wide significant loci in our DM-only GWAS on eGFR ($n_{DM} = 178,691$, combined stage, Methods): we observed 29 genome-wide significant eGFR loci in DM ($P_{DM} < 5 \times 10^{-8}$, Fig. 5, Supplementary Data 10). These included: (i) 27 novel eGFR loci in DM, and (ii) two of the four previously

identified DKD loci among type 1 or type 2 DM patients²² (near *UMOD/PDILT* and *PRKAG2*; $r^2 = 0.60$ and 0.94 , respectively, between eGFR and DKD lead variants). None of the previously identified DKD loci among type 1 DM patients²³ were identified. Two of the 27 novel eGFR loci in DM were detected here as completely novel eGFR loci (near *SH3BP4* and *LOXL4*; also detected by the joint test). The 29 identified eGFR loci in DM included 6 of our 11 difference loci (near *UMOD/PDILT*, *DCDC5*, *SH3BP4*, *NRIP1*, and *LOXL4*).

In silico evidence prioritized 18 genes by protein- or expression-altering variants or as human kidney disease monogene. Genes at GWAS loci for eGFR might pinpoint relevant drug targets for kidney function¹⁸. Dissecting eGFR loci as DM-only, noDM-only, or shared will help define the target population for potential therapy. Gene Prioritization (GPS) was conducted previously¹⁶ for all genes underneath the 424 eGFR-associated loci in a meta-analysis of CKDGen and UKB (i.e., our stage 1 studies) focused on European-ancestry. Since all 7 difference loci were among these 424 loci, we used this established GPS tool to extract *in-silico* functional evidence for the 159 genes

Table 2 Allowing for DM/ noDM difference identified 32 novel eGFR loci.

Shown are 32 novel variants identified with genome-wide significant eGFR association allowing for DM/ noDM-difference by two designs and two approaches (joint or stratified test approaches) using stage 1 ($r_{DM} = 109.993$, $r_{noDM} = 1070.999$), stage 2 ($r_{DM} = 68.698$; $r_{noDM} = 225.114$), or combined data ($r_{DM} = 178.691$, $r_{noDM} = 1.296.113$). (i) Discovery+replication design: 3 variants with P_{DM} , P_{noDM} or $P_{point} < 5 \times 10^{-6}$ in stage 1 were replicated in stage 2 (P_{DM} , P_{noDM} or $P_{point} < 0.05/25 = 0.002$). (ii) Combined stage design: 29 additional variants were identified with P_{DM} , P_{noDM} or $P_{point} < 5 \times 10^{-8}$ in stage 1 + 2 (4 with suggestive difference, $P_{diff} < 0.05/32$). Details are shown in Supplementary Data 6. Source is the identifying test.

Fig. 3 Accounting for potential DM-/noDM-differences identified 32 novel eGFR loci. We searched for novel loci associated with eGFR allowing for DM-/noDM-difference using the joint test or DM-/noDM-stratified tests approaches in combined stage 1 + 2 ($n_{\text{DM}} = 178,691$; total $n_{\text{noDM}} = 1,296,113$). We found 32 novel genome-wide significant eGFR loci ($P < 5 \times 10^{-8}$, >500 kb distant of known eGFR loci compared to previous work^{16,20}): 30 by joint, 17 by noDM-only and 2 by DM-only test. **a** Shown are P -values for eGFR based on joint, noDM-only, and DM-only test over chromosomal position. Highlighted in red are loci with suggestive DM/noDM-difference ($P_{\text{Diff}} < 0.05/34$; corrected for 34 independent variants across 32 loci), blue for loci identified by joint and noDM-only test (15 loci), and purple for loci that were only identified by joint test (upper panel) or noDM-only test (middle panel). Loci were annotated by nearest genes if $P_{\text{Diff}} < 0.10$ or if they were also identified by the discovery+replication design (the latter also indicated by asterisk, Table 2). **b** Shown is a comparison of DM-/noDM-specific eGFR-effect sizes for the 32 novel eGFR locus lead variants. Highlighted in red are the locus names of loci with suggestive DM/noDM-difference ($P_{\text{Diff}} < 0.05/34$; corrected for 34 independent variants across 32 loci). Effect sizes are aligned to the eGFR-decreasing alleles in noDM. Error bars reflect 95% confidence intervals of the estimated genetic effect.

Fig. 4 The variants associated with eGFR in the CUBN locus differ from those associated with urinary albumin-to-creatinine ratio. Shown are P -values for associations at the wider (top) and more narrow (bottom) CUBN locus region for **a** eGFR (joint test P -values, $n_{\text{DM}} = 178,691$ and $n_{\text{noDM}} = 1,296,113$) and **b** urinary albumin-to-creatinine ratio (UACR; P -values from ref. ³⁹, $n = 564,257$). Lead variant for eGFR is rs11254238; color codes variants' correlation r^2 to rs11254238 in all panels.

Fig. 5 DM-only eGFR GWAS identified 29 loci, including 27 novel for eGFR in DM. Shown are eGFR association *P*-values in individuals with DM over chromosomal position in combined stage ($n_{DM} = 178,691$). This DM-specific analysis identified 29 independent eGFR-associated loci in DM. Compared to known DKD loci^{22,23} (i.e., association with eGFR or CKD in type 1 and/or type 2 DM individuals) and known overall eGFR loci^{16,20}, 2 loci are novel for eGFR overall and novel for DKD (red), 24 are novel for DKD but known for eGFR (orange), and 3 are known DKD and known eGFR loci (purple).

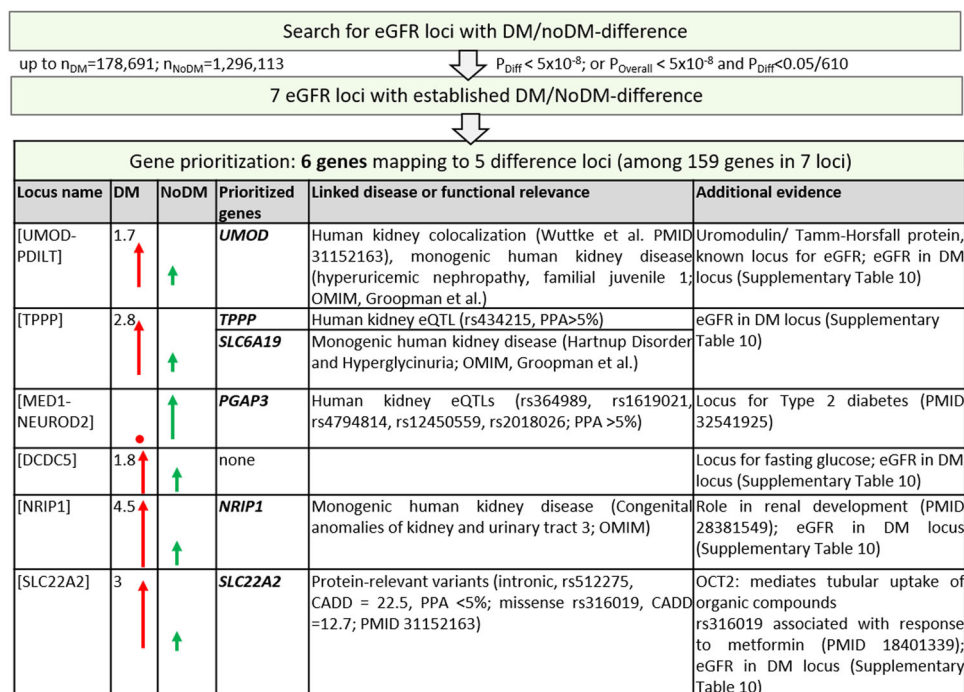

Fig. 6 Gene prioritization highlights six genes at loci with established DM/noDM-difference. Shown are gene prioritization results for the seven loci with established difference (Table 1, Supplementary Fig. 8). We highlighted six genes based on association-driving variants (PPA > 5%) that were deleteriously protein-relevant or expression-modulating, genes that were known as human kidney monogenes (OMIM or ref. ⁷⁸ with subsequent manual curation) and in addition *SLC22A2* due to its known link to metformin response.

at the 7 difference loci: here, we prioritized a gene when it mapped to an association-driving variant (i.e., 99% credible set variant with posterior probability of association $\geq 5\%$, Methods) that was relevant (i) for the protein (with high predicted deleteriousness⁴⁵, i.e., CADD score ≥ 15) or (ii) for expression in kidney tissue (eQTL, false-discovery rate $\geq 5\%$)^{46,47} or (iii) when the gene was a known kidney disease monogene in human (Methods). We found 6 prioritized genes (Fig. 6, Supplementary Fig. 8): (i) *PGAP3* mapping to the locus with noDM-only effect on eGFR (near *MED1/NEUROD2*) and (ii) five genes in loci with more pronounced eGFR-effects in DM but direction-consistent effects in noDM (*TPPP*, *UMOD*, *SLC6A19*, *NRIP1*, and *SLC22A2*).

We also used the same approach as in the previous GPS tool¹⁶ to prioritize the genes underneath the 32 novel eGFR loci (34 independent signals, Supplementary Data 11–15, Supplementary

Table 3, Supplementary Fig. 9): (i) among the 40 genes in the four novel loci with suggestive DM/noDM-difference, 2 genes were human kidney disease monogenes (*HPS1* and *HPSE2*, Fig. 7a); (ii) for the 341 genes in the other 28 novel eGFR loci (i.e., noDM/noDM-difference), 10 genes were prioritized (Fig. 7b): 6 genes contained an association-driving variant that was protein-deleterious (*AUTS2*, *CUBN*, *DVL2*, *RASSF6*, *SLC2A4*, and *ZFP36L1*), one gene mapped to an eQTL in glomerular tissue (*TNIK*), and 3 additional genes were human kidney disease monogenes (*SLC2A2*, *SLC30A9*, and *SLC7A7*). Particularly interesting was an association-driving variant, rs1801232, in *CUBN* that was a missense variant ($r^2 = 0.73$ to eGFR lead variant rs11254238). The missense variant rs17804499 in *RASSF6* had a particularly high probability of being the association-driving variant (posterior probability of association = 86%), which rendered this variant and gene a compelling candidate for

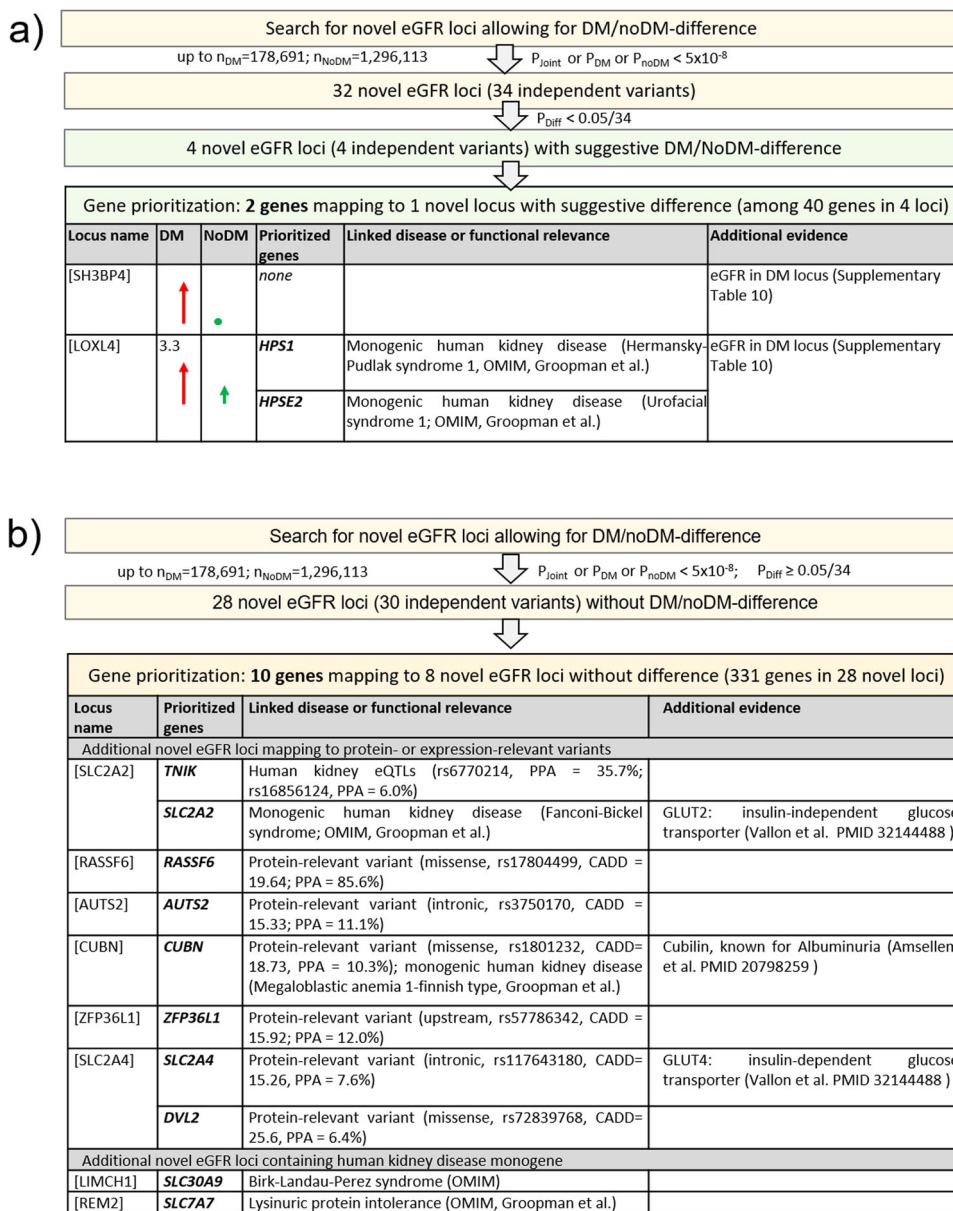

Fig. 7 Gene prioritization highlights 12 genes at novel eGFR loci. Shown are gene prioritization results for the 32 novel eGFR loci (Table 2, Supplementary Fig. 9): **a** for the four novel eGFR loci with suggestive difference, and **b** for the 28 other novel eGFR loci. We highlighted 12 genes based on association-driving variants (PPA > 5%) that were deleteriously protein-relevant or expression-modulating or genes that were known as human kidney monogenes (OMIM or ref. 78 with subsequent manual curation).

functional follow-up. Two genes, *SLC2A2* and *SLC2A4*, encode the glucose transporters GLUT2 and GLUT4 and reside in two novel eGFR loci.

In summary, across the identified seven loci identified with established or suggestive DM-/noDM-difference in eGFR-effects and the 32 novel eGFR loci, we prioritized 18 genes with evidence of protein-deleterious or expression-modulating variants or being human kidney disease monogenes. These genes are compelling candidates for functional follow-up and drug development pipelines.

DM/noDM-stratified weights for GRS show similar explained variance as overall weights. We assessed whether the GRS for eGFR, computed as an effect size weighted sum of eGFR-lowering alleles, could be improved by using DM/noDM-specific eGFR-

effects as weights rather than overall eGFR-effects. We built the GRS based on the previously identified 634 eGFR variants¹⁶ (i.e., identified in stage 1 studies) or based on the seven variants with established DM/noDM-difference using different weighting schemes (overall effects, DM-/noDM-specific effects, or a combination; all weights from stage 1 data). We computed the GRS for each individual in the stage 2 study HUNT (unrelated, European-ancestry; $n_{DM} = 3023$, $n_{noDM} = 25,484$, Fig. 1d, Methods).

Across all weighting schemes, we found no significant DM/ noDM-difference in the 634-variant GRS association with eGFR ($P_{Diff} > 0.05$, Table 3). The 634-variant GRS explained more of the eGFR variance in noDM compared to DM (e.g., $R^2 = 6.0\%$ vs. 4.0% using overall-effect weights). Since the absolute 634-variant GRS effect was similar in DM and noDM (e.g., beta per $sd_{GRS} = -2.54$ versus -2.84 ml/min/1.73 m^2 using overall-effect weights), this larger relative GRS effect in noDM can be attributed

Table 3 Genetic risk score (GRS) association with eGFR and explained variance of eGFR separately for DM and noDM individuals.

GRS	DM $sd_Y = 13.4$ ml/min per $1.73m^2$, $n = 3023$				noDM $sd_Y = 11.8$ ml/min per $1.73m^2$, $n = 25,484$				P_{diff}

Shown are results from GRS analyses separately for DM and noDM individuals. The GRS's were based on the previously established 634 independent eGFR index variants¹⁶ (stage 1 studies) or on the 7 variants with established difference and computed in unrelated individuals of the HUNT study ($n_{DM} = 3023$, $n_{noDM} = 25,484$, one of the stage 2 studies). Three versions of each GRS were computed for each individual: GRS's weighted by overall genetic eGFR-effects, weighted by DM-specific effects or weighted by noDM-specific genetic eGFR-effects. For the GRS based on the 634 variants, a further GRS was computed that was weighted by overall effects for variants without observed DM/noDM-difference and weighted by DM-/noDM-specific effects for variants with observed difference. The association of the GRS on eGFR and the variance explained (R^2) were derived for DM and noDM separately via linear regression with the respective GRS as covariate and eGFR as outcome (not log-transformed, adjusted for age, sex, and principal components, Methods). Also shown is a P -value testing the GRS effect on eGFR for difference between DM compared to noDM. sd standard deviation, se standard error, $beta$ change in eGFR [ml/min/ $1.73m^2$] per standard deviation of the GRSFIGURES.

^aUsing overall weights for loci without observed difference and DM- or noDM-specific weights for loci with significant difference for DM or noDM individuals, respectively.

—at least in part—to the smaller eGFR variance in noDM versus DM (HUNT standard deviation = 11.8 versus 13.4 ml/min/ $1.73m^2$, respectively). Yet, the 7-variant GRS explained more of the eGFR variance in DM compared to noDM (e.g., $R^2 = 0.98\%$ vs. 0.62% using overall-effect weights). The reason for this is that six of the seven variants had larger eGFR-effects in DM than in noDM, which accumulated to a larger absolute GRS effect in DM (e.g., beta per $sd_{GRS} = -1.02$ in DM compared to -0.68 in noDM using overall-effect weights).

When comparing different weighting schemes, we found no notable improvement in R^2 values by using DM-/noDM-specific weights compared to overall weights (Table 3). In the 634-variant GRS, using DM-specific weights even reduced R^2 in DM individuals ($R^2 = 3.1\%$ versus 4.0%). This may be attributable to the larger uncertainty in DM-specific weights estimated from the meta-analysis restricted to DM individuals. For the 7-variant GRS, DM-specific weights slightly increased R^2 in DM individuals, but not markedly ($R^2 = 1.0\%$ versus 0.98%). These findings underscore a similar performance of overall weights and DM-/noDM-specific weights when building a GRS for eGFR. The comparison of the 634-variant with the 7-variant GRS suggests that more differential effect loci and higher precision in DM-specific weights might substantially improve the genetically explained variance also in DM individuals.

Discussion

In this GWAS on eGFR in ~180,000 individuals with DM and ~1.3 million individuals without DM, we established seven loci with significant DM/noDM-differential effects on eGFR near *UMOD/PDILT*, *TPPP*, *MED1/NEUROD2*, *CSRNPI*, *DCDC5*, *NRPI1*, and *SLC22A2*. We also identified 32 novel eGFR-associated loci when allowing for potential difference, including four loci with a suggestive difference near *SH3BP4*, *LOXL4*, *ALPL*, and *PIK3CG*. The 11 loci with established or suggestive difference included two loci with DM-only effects on eGFR (near *CSRNPI*, *SH3BP4*), one with noDM-only effect (near *MED1/NEUROD2*), and all others showed more pronounced effects in DM compared to noDM. Our GWAS focused on DM individuals confirmed two known DKD loci, but also identified 27 novel loci for eGFR in

DM, which make these potential new DKD loci. The DM-/noDM-stratified GRS analyses showed no improvement in explained trait variance when using DM-/noDM-stratified weights, but the seven identified DM/noDM-differential eGFR-effects explained more of the eGFR variance in DM individuals than in noDM individuals.

Our gene prioritization at the 11 loci with DM/noDM-difference and at the 28 other novel eGFR loci highlighted 18 genes: 10 genes mapped to eGFR-association-driving variants that were deleteriously protein-relevant or eQTLs in kidney tissue, which suggests them as potential drug targets to alter eGFR. Further eight genes were prioritized because they were known as human kidney disease monogenes, which made them plausible causal genes for these common variant findings. Particularly interesting was *CUBN* in a novel eGFR locus. The *CUBN* locus is the GWAS locus with the strongest effect on UACR³⁹ and microalbuminuria⁴⁰ and identified here for eGFR at genome-wide significance, but respective lead variants for eGFR and UACR are uncorrelated. The lead variant for eGFR, rs11254238, is highly correlated with a variant that alters the encoded protein, cubilin (rs1801232, $r^2 = 0.91$). We observed a twice as large effect on eGFR in DM compared to noDM in both discovery and replication data, but not statistically significantly different. This is in line with previously observed larger *CUBN* variants' effects on microalbuminuria⁴⁰ and UACR^{41,48} in DM, which provides further evidence for an interaction of *CUBN* with DM status on kidney function. In fact, our previous sequencing of the *CUBN* gene found rare variants in *CUBN* that were associated with higher UACR and with better eGFR⁴⁹. Our study now reports such a parallel association between UACR and eGFR now also for a common variant at the genome-wide significance levels. Together, our results provide further support for the importance to assess the physiological role of *CUBN* by functional studies not only for microalbuminuria, but also for finding pathophysiological explanations related to impaired filtration rate.

The *RASSF6* gene has been studied in relation to the kidney as well: *RASSF6* mediates apoptosis in various cells⁵⁰. It is shown to be expressed in the slit diaphragm in glomeruli and the apical membranes in proximal renal tubular epithelial cells of rat

kidney. The same animal study suggests the involvement of the *RASSF6* pathway in contrast-induced nephropathy. Thus, the novel detection of the *RASSF6* locus for eGFR here and the lead variant, rs17804499, being protein-altering and with 86% probability causal render *RASSF6* a compelling candidate for the functional follow-up to help understand its role in kidney function that is elusive so far.

Another interesting gene was *PGAP3* in the *MED1-NEUROD2* locus, which mapped to an expression-modulating variant that was associated with eGFR in noDM, but not in DM individuals. *PGAP3* is a known gene for CKD and eGFR: eQTL analyses showed colocalization of the association signal with *PGAP3* expression⁵¹. *PGAP3* knockout mice developed larger glomeruli with deposition of immunoglobulins⁵², although we acknowledge that this does not provide a mechanistic explanation for its association with eGFR. Eventually, if causal genes at eGFR loci with significant differences by DM status will be advanced as drug targets for reno-protective therapies, the knowledge about DM- or noDM specificity of the eGFR association can help define the target group for potential subsequent therapy, as DM-only, noDM-only, or both.

The difference in SNP effects between DM and noDM can be interpreted as SNP-by-DM-status interaction effect. To our knowledge, our study is the first genome-wide search for SNP-by-DM-status interaction effects for eGFR. Sensitivity analyses indicated that the observed differences were neither biased from the stratified modeling, nor from log-transformed eGFR, and the SNP-by-DM-status interaction was not explained by SNP-interaction with age, sex, hypertension, or body-mass-index⁵³. The seven loci with an established difference are known loci for eGFR^{16,20}. To our knowledge, the significant DM/noDM-differential effects for eGFR or eGFR-based CKD were identified here for the first time, except for the *UMOD-PDILT* locus²¹. At *UMOD-PDILT*, a well-known kidney function locus^{16,20}, the two-fold higher eGFR effect in DM compared to noDM confirmed previous observations for eGFR^{21,54} and CKD⁵⁵. Very interesting was the *TPPP* locus, where the three-fold higher eGFR effect in DM now draws attention to a locus that was just one of the hundreds of small effects eGFR loci. The lead variant for the difference, rs434215, modulates *TPPP* expression in tubulointerstitial tissue⁴⁶, but the role of *TPPP* in diabetes and kidney disease is yet unknown. Previous studies on *TPPP* focused on the nervous system: *TPPP* is highly expressed in the brain and shown to affect neural microtubules⁵⁶.

Our GWAS on eGFR in DM provides a link to the genetics of DKD. Previous GWAS for DKD analyzed eGFR or eGFR-based CKD in type 1 and/or type 2 DM individuals^{22,23}. Our GWAS in >178,000 DM individuals was 4- to 7-fold larger. These DM individuals were mostly from population-based studies of adult individuals. As such, the proportion of type 1 DM among DM individuals analyzed here reflects the proportion of type 1 DM of 5–10% among adult DM individuals⁵⁷. Due to the substantially larger number of type 2 DM individuals, the identified DM/noDM-differential effects on eGFR may mostly reflect differences between type 2 DM versus noDM. A better distinction by type of DM would require more granular data focusing on the distinction between these two major diabetes groups and substantially larger data on type 1 DM. While the use of self-reports or one-time measurements of glucose or HbA1c to define DM here is typical also for GWAS on DM^{19,58}, this implies heterogeneity in the DM definition and may include some individuals without clinically manifest DM.

Yet, our 29 loci with genome-wide significant association with eGFR in DM confirmed two of eight previously identified DKD loci^{22,23} and the 27 other are compelling new candidate loci for further analyses in studies specialized on DKD patients. A large sample size eGFR GWAS with a more heterogeneous spectrum of

DM can be a powerful complementary approach to focused searches in DKD patients^{22,23}. Several prioritized genes mapped to these novel eGFR loci in DM: *TPPP* already mentioned above and *SLC6A19*, *NR1P1*, *HPS1* as well as *HPSE2* with strong monogenic impact on kidney. All these genes reside in loci with more pronounced eGFR-effects in DM compared to noDM, but none of these effects was DM-only.

Our GWAS allowing for DM/noDM-differential effects identified 32 novel eGFR-associated loci compared to previous GWAS^{16,20}. Some of our novel loci might be identified due to increased power by ~20% increased sample size or due to chance by using alternative statistical tests. However, four of the novel loci showed suggestive DM/noDM-difference, suggesting that their identification was facilitated by using tests allowing for differential effects⁵⁹. The four suggestive difference loci included one locus, near *SH3BP4*, with eGFR effect only in DM.

In contrast to hundreds of loci found in GWAS for eGFR, the eGFR loci with significant DM/noDM-difference were few. This suggests a largely shared genetics of kidney function between DM and noDM individuals, which has an important implication for drug development: most drug interventions aimed at altering eGFR should thus be effective among persons with and without DM. This is mirroring what is observed for SGLT2 inhibitors—a medication originally developed for individuals with DM that is now also being tested for reno-protection among individuals without DM¹³. While our GWAS here is, to date, the largest for eGFR in DM individuals, we still might have missed loci with effects in DM-only. Power for interaction effects is generally smaller than for overall effects⁶⁰, and particularly reduced when one subgroup, like DM, is substantially smaller (~10%) than the other²⁸. Future work with an increased sample size might detect more eGFR loci with differences by DM status, especially those with effects in DM-only. This GWAS included mostly European individuals and our findings require replication in non-European ancestries⁶¹, particularly because of the large differences in DM prevalence across ancestries⁶².

In summary, our results highlight the existence of DM- and noDM-specific genetic effects on kidney function, but emphasize that the majority of eGFR locus associations do not differ between individuals with and without DM. Larger DM-/noDM-stratified data on eGFR in the future will improve the detectability of differential effect loci and the precision of DM-specific weights. This might also improve DM-/noDM-stratified GRS prediction of eGFR. The identified eGFR loci with difference between DM- and noDM individuals include loci with effects only in DM as well as loci with effects in noDM. This has highly relevant implications, if the respective genes are advanced as a drug target: the specificity of the association might help sharpen the target group for such potentially arising drug therapies.

Methods

Definition of the outcome eGFR and study-specific participant information.

GFR was estimated in all study participants in all studies using serum creatinine measurements via the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula²⁰. Study-specific information on the utilized assay and year of measurement is given in Supplementary Data 1. We used the R package *nephro*⁶³, winsorized at 15 and 200 ml min⁻¹ per 1.73 m², and logarithmized using a natural logarithm. For a better interpretation of effect size, we there used eGFR on the original scale in GRS analyses. Study-specific information on study design, sample size, sex and age, utilized serum creatinine assay, year of measurement, and average eGFR is given in Supplementary Data 1.

Each study is conducted according to the declaration of Helsinki; local ethics committees approved research protocols and participants provided written informed consent.

Definition of DM status. DM of each study participant at the time point of the serum creatinine measurement was defined either (i) as fasting plasma glucose ≥126 mg/dl (7.0 mmol/L) or diabetes therapy, or (ii) (fasting glucose unavailable)

as non-fasting plasma glucose ≥ 200 mg/dl (11.0 mmol/L) or diabetes therapy, or (iii) (glucose unavailable) as self-reported diabetes. For UKB, DM was defined as HbA1c ≥ 48 mmol/mol ($\geq 6.5\%$) or diabetes therapy (i.e., A10 ATC codes obtained from⁶⁴).

Study-specific GWAS analyses stratified by DM status. We distributed an analysis plan to the 72 participating studies of the CKDGen consortium. Each study conducted analyses separately for individuals with DM and individuals without DM. All studies imputed genotypes to the Haplotype Reference Consortium v1.1 (HRC) or 1000 Genomes Project phase 3 v5 (1000Gp3v5) ALL or phase 1 v3 (1000Gp1v3) ALL panel. Each study conducted linear regression GWAS on log(eGFR) using natural logarithm, an additive genotype model as well as adjusted for sex, age, and other study-specific covariates. Details on study-specific genotyping, imputation, and GWAS were described previously for CKDGen²⁰. For UKB, we utilized the fastGWA tool⁶⁵ to conduct GWAS for log(eGFR) based on linear mixed models while accounting for sex, age, age \times sex, age² \times sex, and 20 genetic principal components and assuming an additive genetic model, which allowed to include related individuals in the GWAS⁶⁵. For stage 2 studies, MVP, MGI, and HUNT, the same analysis plan was distributed. Details on genotyping, imputation, and GWAS in UKB as well as for stage 2 studies are shown in Supplementary Data 1. For quality control, we excluded variants with low imputation quality, $\text{Info} < 0.6$, or rare variants with minor allele frequency, $\text{MAF} < 0.1\%$. We utilized the software packages GWAToolbox⁶⁶ and EasyQC⁶⁷ for the quality control of study-specific GWAS results. We conducted a correction for genomic control lambda of the results stratified by diabetes status.

DM/noDM-stratified GWAS meta-analyses. In stage 1 of our analysis, separately in DM ($n_{\text{DM}} = 88,829$) and noDM ($n_{\text{noDM}} = 620,665$) strata, we conducted fixed-effect inverse-variance weighted meta-analyses of 72 GWAS of log(eGFR) using meta⁶⁸, and then meta-analyzed these results with DM/noDM-stratified GWAS from UKB ($n_{\text{DM}} = 21,040$; $n_{\text{noDM}} = 414,628$; European only). To adjust for population stratification within studies, we applied genomic control (GC) correction⁶⁹ to each study prior to the meta-analysis. We applied a second GC correction to the DM- and noDM stage 1 meta-analysis results (GC lambda = 1.02 and 1.20, respectively). We excluded variants that were present only in ≤ 36 stage 1 studies ($\leq 50\%$) and variants with a cumulative minor allele count of < 400 in the stage 1 meta-analyses. In summary, 109,869 individuals with DM and 1,035,190 with noDM were included in stage 1. We followed variants identified at stage 1 in independent stage 2 meta-analyses. For stage 2, we included DM/noDM-stratified GWAS on log(eGFR) from MVP ($n_{\text{DM}} = 57,430$, $n_{\text{noDM}} = 122,966$, hospital-based), MGI ($n_{\text{DM}} = 7469$, $n_{\text{noDM}} = 36,558$, hospital-based) and HUNT ($n_{\text{DM}} = 3799$, $n_{\text{noDM}} = 65,590$, population-based), totalling 68,698 individuals with DM and 225,114 with noDM, all of European-ancestry. Again, we applied study-specific GC correction prior to the meta-analysis and a second GC correction⁶⁹ to the stage 2 meta-analysis results (GC lambda = 1.00 and 1.02 for DM- and noDM, respectively). To maximize power for locus identification, we combined the double GC-corrected stage 1 and 2 meta-analysis separately by DM status via fixed-effect inverse-variance weighted meta-analyses of the two sources using meta⁶⁸. The GC lambda in this final meta-analysis was comparable to previous GWAS^{16,70} (GC lambda = 1.03 and 1.15, respectively). The DM-/noDM-specific summary statistics (stratified GWAS) for each variant genome-wide served to investigate potential DM-/noDM-differential genetic effects on log(eGFR) without making any assumptions on the DM association with any other covariate⁷¹. These DM-/noDM-specific summary statistics on genetic variants associated with log(eGFR) enabled the implementation of all the following statistical tests to search for DM/noDM-difference loci or novel loci allowing for difference as described below.

Approaches to search for DM/noDM-difference in genetic effects on eGFR.

We used the meta-analyzed SNP-specific summary statistics, to test for difference in eGFR-effects between DM and noDM. For this, we applied a difference test for each variant using

$$Z_{\text{diff}} = \frac{\hat{\beta}_{\text{DM}} - \hat{\beta}_{\text{noDM}}}{\sqrt{se_{\text{DM}}^2 + se_{\text{noDM}}^2 - 2r_{\text{diab}}se_{\text{DM}}se_{\text{noDM}}}} \quad (1)$$

where $\hat{\beta}_{\text{DM}}$ and $\hat{\beta}_{\text{noDM}}$ are the genetic effect estimates for eGFR in DM or noDM from the stratified GWAS meta-analysis, respectively, and corresponding standard errors se_{DM} and se_{noDM} . The term r_{diab} reflects the correlation between $\hat{\beta}_{\text{DM}}$ and $\hat{\beta}_{\text{noDM}}$ across all variants (Spearman correlation coefficient, $r_{\text{diab}} = 0.14$).

To search genome-wide for eGFR loci with DM-/noDM-differential effects, we applied two approaches^{24,37}: (i) a genome-wide difference test ($P_{\text{Diff}} < 5 \times 10^{-8}$, difference test approach), and (ii) a search for genome-wide significant association with overall eGFR followed by a difference test in the same data ($P_{\text{Overall}} < 5 \times 10^{-8}$ and $P_{\text{Diff}} < 0.05/k$, k = number of followed SNPs, overall+difference test approach). The two approaches complement each other in terms of power to detect difference loci that depend on the magnitude and DM-/noDM specificity^{24,37}. We implemented the approaches in two designs: first, we applied a discovery +replication design, where we searched for significant differences in the stage 1 meta-analysis and moved the selected SNPs to a replication stage using the stage 2

meta-analysis (applying a Bonferroni-corrected alpha-level accounting for the SNPs tested). Second, to make full use of stage 1 and stage 2 data, we searched for differences in stage 1 + 2 meta-analysis combined (combined stage design). We utilized the R package EasyStrata⁷² to apply the difference test approaches to the DM/noDM-stratified meta-analysis results.

Approaches to search for eGFR loci allowing for DM/noDM-differences. By allowing for differences between DM and noDM in SNP-effects on eGFR, one can possibly detect novel loci that have been masked in analyses on overall eGFR (without DM-status stratification). Again, we used the meta-analyzed SNP-specific summary statistics to apply two approaches to search for novel eGFR loci allowing for difference: (i) a screen using a two degrees of freedom joint test ($P_{\text{joint}} < 5 \times 10^{-8}$, joint-test approach)³⁸ derived from a χ^2 -test using³⁸

$$C_{\text{joint}} = \left(\frac{\hat{\beta}_{\text{DM}}}{se_{\text{DM}}} \right)^2 + \left(\frac{\hat{\beta}_{\text{noDM}}}{se_{\text{noDM}}} \right)^2 \quad (2)$$

where $\hat{\beta}_{\text{DM}}$ and $\hat{\beta}_{\text{noDM}}$ are the genetic effect estimates for eGFR in DM or noDM from the stratified GWAS meta-analysis, respectively, and corresponding standard errors se_{DM} and se_{noDM} ; and (ii) a on eGFR association in individuals with or without DM separately (stratified tests approach, $P_{\text{DM}} < 5 \times 10^{-8}$ or $P_{\text{noDM}} < 5 \times 10^{-8}$). Analogously to the search for difference loci, we applied two-stage designs, the discovery+replication, and the combined stage designs. We utilized the R package EasyStrata⁷² to apply the joint and stratified test approaches to the DM/noDM-stratified meta-analysis results.

Variant selection and region definition. In order to derive non-overlapping locus regions and locus lead variants, we clumped genome-wide significant variants from the respective test results ($P_{\text{Diff}} < 5 \times 10^{-8}$, $P_{\text{joint}} < 5 \times 10^{-8}$, $P_{\text{DM}} < 5 \times 10^{-8}$, or $P_{\text{noDM}} < 5 \times 10^{-8}$) as done previously¹⁶: the most significant variant was selected genome-wide (first locus lead variant) and the corresponding locus was defined as the smallest physical interval on the corresponding chromosome containing this variant such that there were no genome-wide significant variants within 500 kb outside the two borders. Omitting the identified locus, we repeated the procedure until no further genome-wide significant variants were detected. By this, a locus region is defined by adding ± 250 kb to the first and last genome-wide significant variant of an identified locus. This procedure also ensured non-overlapping loci. A locus was considered to be known for eGFR from previous GWAS, if it overlapped with one of the 427 known eGFR loci (424 from ref. 16, 3 additional from ref. 20). If a locus is not known, we call it a novel eGFR locus. For the identified variants, we assessed between-study heterogeneity based on the CKDGen meta-analysis using a Chi-Squared test and an I^2 statistic⁷³ and verified the association statistics with regards to abnormal or unusually large effect sizes.

GCTA analyses to identify independent secondary signals within loci. To evaluate whether there were multiple independent signals within locus, we conducted approximate conditional analyses with GCTA⁷⁴ for each identified locus. These analyses were based on European-ancestry individuals, since appropriate trans-ethnic linkage disequilibrium (LD) reference panels were limited. As LD reference panel, we used a random subset of 20,000 unrelated individuals of European-ancestry from UKB, as done previously¹⁶. To obtain independent signals for associations derived by the difference test, the joint test, or DM- or noDM-specific association tests, we applied a stepwise approach: we conditioned via GCTA analysis on the, respectively, observed lead variant in DM and noDM separately and, second, derived DM/noDM-specific conditioned results for the locus. Separately for DM and noDM, we ensured whether any of the conditioned DM- or noDM-specific associations in the locus showed genome-wide significant association at $P_{\text{DM,Cond}} < 5 \times 10^{-8}$ or $P_{\text{noDM,Cond}} < 5 \times 10^{-8}$. For loci derived by the difference test or the joint test, we applied the difference test or joint test, respectively, to the conditioned DM/noDM estimates to infer whether additional signals showed significant differences or joint effects ($P_{\text{Diff,Cond}} < 5 \times 10^{-8}$ or $P_{\text{joint,Cond}} < 5 \times 10^{-8}$).

Prioritization of variants and genes. For each variant within each identified signal, we derived the variants that were the most likely to drive the association. For this, we calculated approximate Bayes factor and posterior probabilities of association (PPA) based on Z-scores using the Kichaev method⁷⁵. We calculated PPAs based on unconditioned or conditioned summary statistics depending on whether the locus showed only one or multiple independent signals, respectively. Then, we obtained 99% credible sets of variants by sorting the variants within each signal by descending PPA and then summing up PPAs until a cumulative PPA of 99% was reached. To prioritize genes, we used the results from the Gene Prioritization (GPS) published previously¹⁶ for known eGFR loci and generated the GPS de novo for novel eGFR loci accordingly: we queried each gene underneath identified loci and prioritized the gene when it mapped to a 99% credible set variant that was protein-relevant with high predicted deleteriousness (CADD⁴⁵ PHRED-Score ≥ 15) or expression-relevant in kidney tissue (eQTL, NEPTUNE⁴⁶, or GTEx v7⁷⁶, false-discovery rate, $\text{FDR} < 5\%$ for the eQTL) and for splice quantitative trait loci in kidney tissue (sQTL)⁷⁶ ($\text{FDR} < 5\%$ for the sQTL). We also prioritized genes that

were known as human kidney disease monogene: for this, we queried each gene at identified loci for a documented kidney phenotype in human as done previously¹⁶ (Online Mendelian Inheritance in Man® database, OMIM⁷⁷ or Groopman et al.⁷⁸) with additional manual curation by expert review to focus on kidney disease monogenes.

GRS analyses. GRS analyses based on the previously identified 634 eGFR variants¹⁶ and based on the variants identified for DM-/noDM-difference on eGFR were conducted in unrelated European-ancestry individuals from HUNT ($n_{DM} = 3023$, $n_{noDM} = 25,484$, stage 2 study). For each individual, the GRS was computed as the weighted sum of eGFR-lowering alleles across the 634 variants applying three different weighting schemes: (i) weighted by the respective overall per-variant effect as derived previously (i.e., estimated in CKDGen and UK Biobank, our stage 1 data¹⁶) (ii) weighted by the variant's DM-/noDM-specific effects as derived here in stage 1 depending on whether the individual in HUNT had DM or noDM, respectively (and vice versa), (iii) weighted by the variant's DM-/noDM-specific effect from stage 1 for HUNT individuals with DM/noDM, respectively, when the variant was among the seven with an identified significant difference, and weighted by the overall-effect size otherwise. By this, the GRS association analyses conducted in a stage 2 study were independent of the variant identification and weight estimation, which were based on stage 1 studies. Separately for individuals with and without DM, we estimated the association of the GRS on eGFR by linear regression (original scale; adjusted by sex, age, and genetic principal components). We judged the GRS effect per standard deviation of the GRS and the eGFR variance explained by the GRS separately in DM and noDM separately.

Reporting summary. Further information on research design is available in the Nature Research Reporting Summary linked to this article.

Data availability

Summary genetic association results for the DM-status-specific meta-analyses for log(eGFRcrea) can be downloaded from <https://ckdgen.imbi.uni-freiburg.de/>. All other data are available from the corresponding author on reasonable request.

Code availability

The analysis plan can be downloaded from https://ckdgen.eurac.edu/mediawiki/index.php/CKDGen_Round_4_EPACTS_analysis_plan and the phenotype command line script from <https://github.com/genepi-freiburg/ckdgen-pheno>. All other code is available from the corresponding author on reasonable request.

Acknowledgements

The Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) supported the meta-analysis—Project-ID 387590280—SFB1350 (Subproject C6 to I.M.H.). A.M.H., B.R., and R.T. were supported by VACSR&D MVP grant CX001897. This research is based on data from the Million Veteran Program, Office of Research and Development, Veterans Health Administration, and was supported by VACSR&D MVP grant CX001897 (A.M.H.). This publication does not represent the views of the Department of Veterans Affairs or the United States Government. We conducted this research using the UK Biobank resource under the application number 20272. We thank Paola Bilani for collecting author information. Extended acknowledgements are provided in Supplementary Note 4 for all studies, in Supplementary Note 5 for MVP and in Supplementary Note 6 for LifeLines.

Author contributions

T.W., H.R., A.Teu., M.Go., B.R., K.Stan., R.T., U.Th., C.A.B., A.Hu., F.K., A.Köt., C.P., and I.M.H. wrote the manuscript. T.W., H.R., A.Teu., M.Go., C.A.B., A.Köt., C.P., and I.M.H. designed the study. Funding

Open Access funding enabled and organized by Projekt DEAL.

Competing interests

GlaxoSmithKline and Merck & Co employed A.Y.C. Janssen Pharmaceuticals and GlaxoSmithKline employed D.M.W. K.B.S., L.M.Y.-A. and M.A.L. are full-time employees of GlaxoSmithKline. M.S. receives funding from Pfizer Inc. for a project not related to this research. J.Ä. reports personal fees from AstraZeneca, Boehringer Ingelheim and Novartis, outside of the submitted work. D.F.G., H.H., K.S., P.S., G.S. and U.T. are employees of deCODE/Amgen Inc. Kevin Ho received support by Fresenius Medical Care North America. M.K. is employed with Synlab Holding Deutschland GmbH. W.K. reports consulting fees from AstraZeneca, Novartis, Pfizer, The Medicines Company, DalCor, Kowa, Amgen, Corvidia, Daiichi-Sankyo, Genentech, Novo Nordisk, Esperion, OMEICOS, LIB Therapeutics, speaker honoraria from Amgen, AstraZeneca, Novartis, Berlin-Chemie, Sanofi, and Bristol-Myers Squibb, and grants and non-financial support from Abbott, Roche Diagnostics, Beckmann, and Singulex, outside the submitted work. C.L. received Grants/ Research Support from Bayer Ag/ Novo Nordisk, Husband works for Vertex. As of January 2020, A.M. is an employee of Genentech, and a holder of Roche stock. W.M. is employed with Synlab Holding Deutschland GmbH. D.O.M.-K. is a part-time research physician at Metabolon, Inc. M.A.N. was supported by a consulting contract between Data Tecnica International LLC and the National Institute on Aging

(NIA), National Institutes of Health (NIH), Bethesda, MD, USA and consults for a number of small biotech and pharma. M.L.O. received grant support from GlaxoSmithKline during conduct of the study and received support from Novartis, Merck, Amgen, and AstraZeneca. L.S.P. has served on Scientific Advisory Boards for Janssen, and has or had research support from Merck, Pfizer, Eli Lilly, Novo Nordisk, Sanofi, PhaseBio, Roche, Abbvie, Vascular Pharmaceuticals, Janssen, GlaxoSmithKline, and the Cystic Fibrosis Foundation. He is also a cofounder, Officer and Board member and stockholder for a company, Diasyst, Inc., which markets software aimed to help improve diabetes management. A.I.P. and D.F.R. are employees of Merck Sharp Dohme Corp. Bruce.M.P. serves on the steering committee of the Yale Open Data Access Project funded by Johnson & Johnson. P.R. received fees to his institution for research support from AstraZeneca and Novo Nordisk; for steering group participation from AstraZeneca, Gilead, Novo Nordisk, and Bayer; for lectures from Bayer, Eli Lilly and Novo Nordisk; and for advisory boards from Sanofi and Boehringer Ingelheim outside of this work. V.S. has received a modest honorarium from Sanofi for consulting. He also has ongoing research collaboration with Bayer Ltd. (all outside of the present study). L.W. received institutional grants from GlaxoSmithKline, AstraZeneca, BMS, Boehringer-Ingelheim, Pfizer, MSD and Roche Diagnostics. H.W. has received grant support paid to the institution and fees for serving on Steering Committees of the ODYSSEY trial from Sanofi and Regeneron Pharmaceuticals, the ISCHEMIA and the MINT studies from the National Institutes of Health, the STRENGTH trial from Omthera Pharmaceuticals, the HEART-FID study from American Regent, the DAL-GENE study from DalCor Pharma UK Inc., the AEGIS-II study from CSL Behring, the SCORED and SOLOIST-WHF from Sanofi Aventis Australia Pty. Ltd., and the CLEAR OUTCOMES study from Esperion Therapeutics. M.P. is partly funded by the study FinnGen (www.finnngen.fi), which is jointly funded by a Finnish Governmental agency Business Finland and thirteen international pharmaceutical companies: Abbvie, AstraZeneca, Biogen, Boehringer Ingelheim, Bristol-Myers Squibb, Genentech, a member of the Roche Group, GlaxoSmithKline (GSK), Janssen, Maze Therapeutics, MSD (the tradename of Merck & Co., Inc, Kenilworth, NJ USA), Novartis, Pfizer and Sanofi. C.C.K. is an Editorial Board Member for *Communications Biology*, but was not involved in the editorial review of, nor the decision to publish this article. The remaining authors declare no competing interests.

Supplementary Figure 1. Three eGFR loci were identified with differential effects by diabetes status in stage 1 and replicated in stage 2

We searched for DM/noDM-differential genetic associations on eGFR using the difference test approach and the overall+difference approach in stage 1 (CKDGen and UKB, $n_{DM}=109,993$, $n_{noDM}=1,070,999$). Three difference loci were identified and replicated. a) Shown are difference test P-values over chromosomal base position (Manhattan plot) highlighting the one identified by the difference test approach (red, $P_{Diff}<5\times 10^{-8}$) and the two loci identified by the overall+difference test approach (orange, $P_{Diff}<8.2\times 10^{-5}=0.05/610$, corrected for 610 with stage 1 $P_{Overall}<5\times 10^{-8}$ as published previously ²). Loci are annotated by the name(s) of the nearest gene(s). b) Shown is the distribution of observed versus expected DM/noDM-difference P-values (QQ plot). The genomic control inflation factor for the stage 1 difference test was $\lambda_{GC}=1.04$.

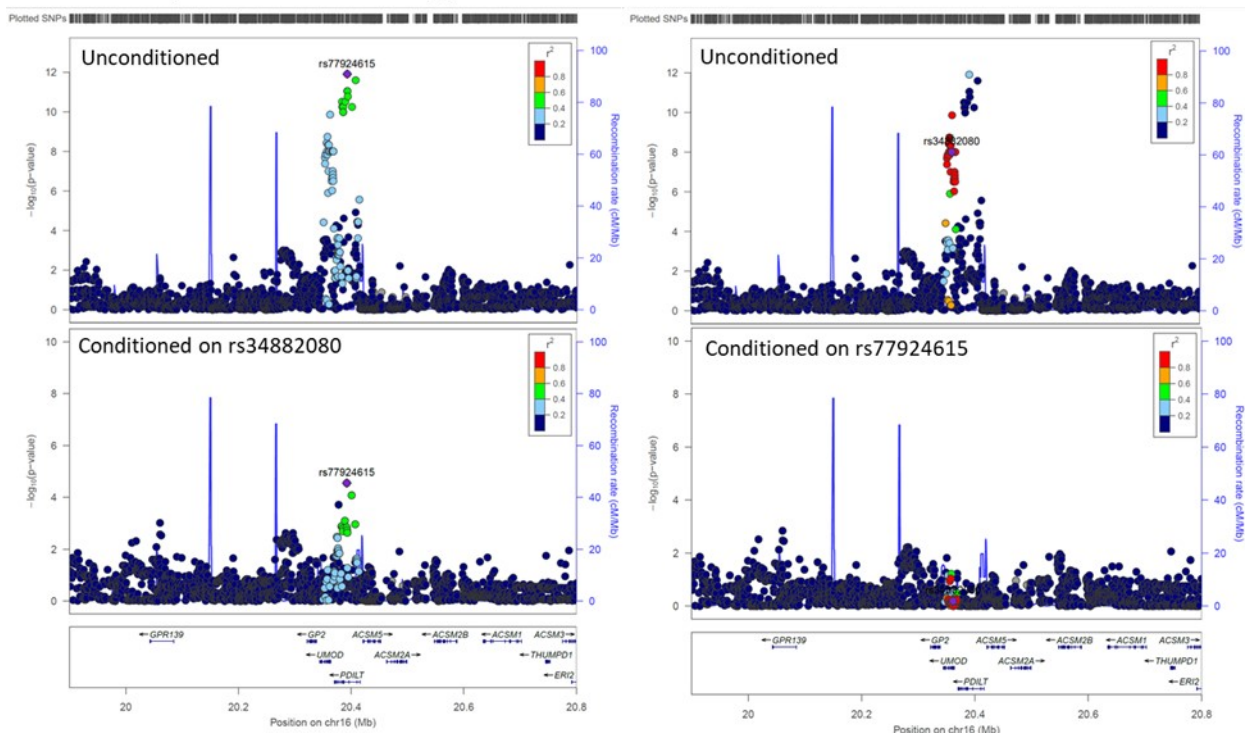

Supplementary Figure 2. Unconditioned and conditioned difference P Values for the *UMOD/PDILT* locus.

We computed difference P-Values at the *UMOD/PDILT* locus unconditioned and conditioned for the two previously identified independent index variants rs77924615 or rs34882080³, respectively, in stage 1 ($n_{DM}=109,993$, $n_{noDM}=1,070,999$). Shown are difference P-values in regional association plots for each variant in *UMOD-PDILT* locus. a) color-coding correlation to rs79924615 unconditioned (upper panel) and conditioned on rs34882080 (lower panel); and b) color-coding correlation to rs34882080 unconditioned (upper panel) and conditioned on rs79924615 (lower panel). This highlights that the rs77924615 showed a significant difference even after conditioning for rs34882080 but the rs34882080 difference disappeared after conditioning for rs77924615.

a) rs77924615 signal

b) rs34882080 signal

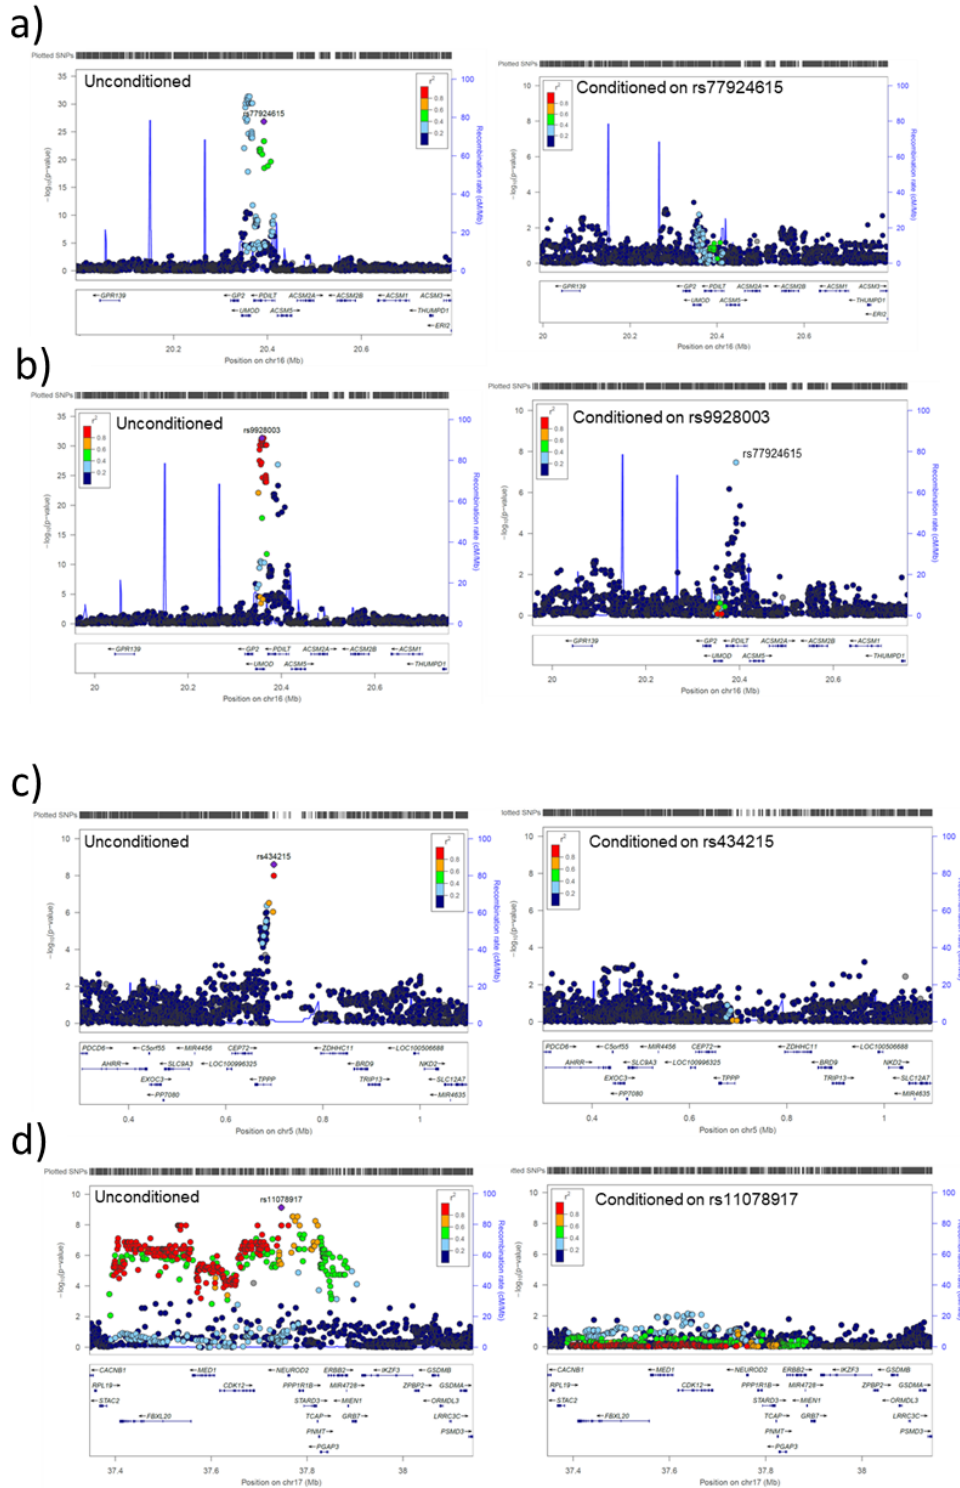

Supplementary Figure 3. Distribution of difference P values in stage 1+2 combined.

Shown is observed difference P-values versus expected (QQ plot) for the combined stages 1+2 ($n_{DM}=178,691$; $n_{nodM}=1,296,113$). The genomic control inflation factor for the stage 1+2 difference test was again $\lambda_{GC}=1.04$.

Supplementary Figure 4. Unconditioned and conditioned regional difference P-values for the seven identified difference loci in stage 1+2.

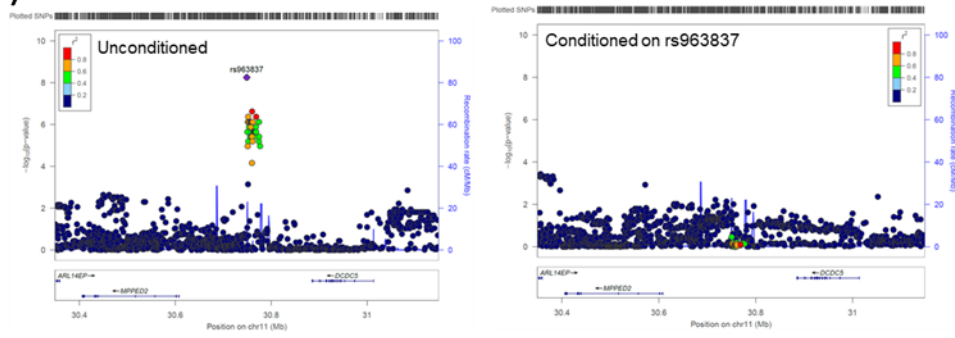

We computed difference P-values for each of the seven identified difference loci unconditioned and conditioned on the respective lead variant based on combined stage 1+2 ($n_{DM}=178,691$; $n_{nodM}=1,296,113$). Shown are unconditioned and conditioned difference P-values for the locus near a) *UMOD/PDILT*, conditioned on stage 1 lead variant rs77924615; b) *UMOD/PDILT*, conditioned on stage 1+2 lead variant rs9928003; c) *TPPP*; d) *MED1-NEUROD2*; e) *CSRN1P1*; f) *DCDC5*; g) *NR1P1*, and h) *SLC22A2*.

e)

g)

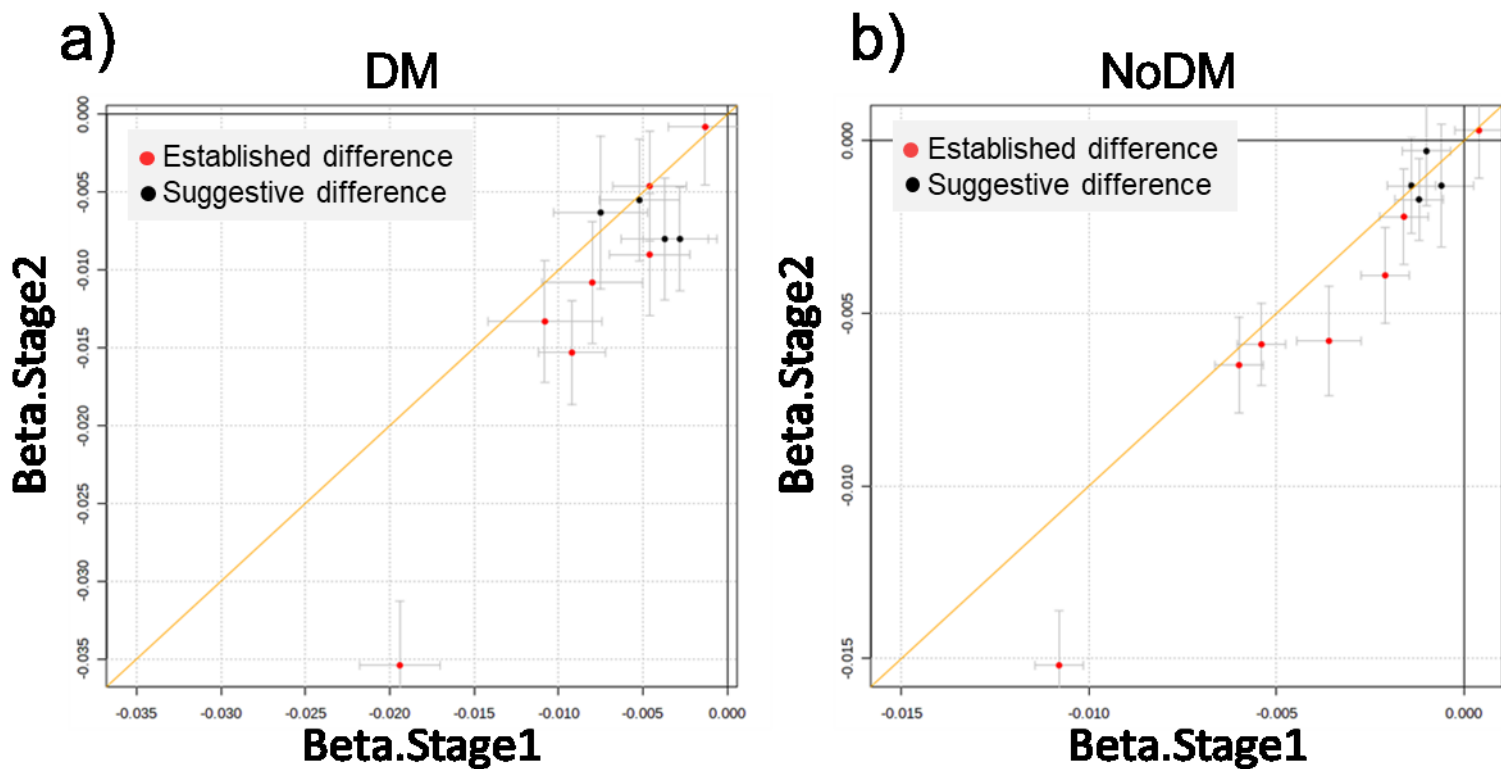

h)

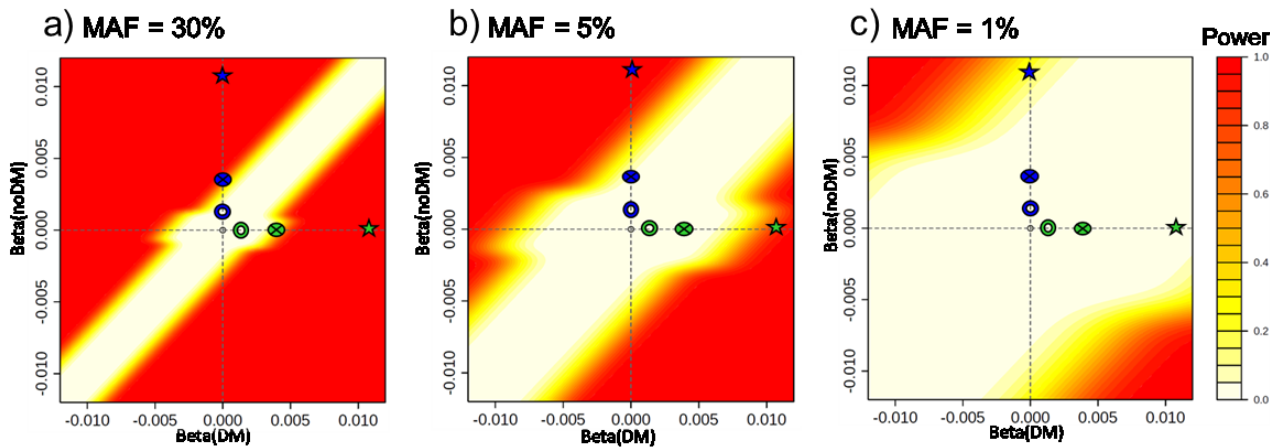

Supplementary Figure 5. Stage 1 and stage 2 effect sizes for eGFR by DM and noDM for the 11 differential loci.

Shown are comparisons of effect sizes from stage 1 ($n_{DM}=109,993$; $n_{noDM}=1,070,999$) and stage 2 ($n_{DM}=68,698$, $n_{NoDM}=225,114$) for a) individuals with DM; or b) individuals with noDM. Indicated in red are the 7 loci identified by the difference screens (from **Table 1**, established difference) and in black the 4 additional novel eGFR loci with suggestive difference (from **Table 2**). Error bars reflect 95% confidence intervals of the estimated genetic effect.

Supplementary Figure 6. Power to detect DM/noDM-differential effects for eGFR for varying effect sizes in DM and noDM.

Based on our stage 1+2 sample size of ~180,000 individuals with DM and ~1,300,000, we computed the power to identify DM/noDM-differential eGFR associations by the difference test approach or the overall+difference test approach for varying log eGFR effect sizes in DM (x-axis) and noDM (y axis). Shown are heatmaps indicating the power (color code) for the respective DM-/noDM effect size for three different minor allele frequencies (MAF). a) common variant (30% minor allele frequency, MAF), b) low frequency variant (5% MAF), and c) rare variant (1% MAF). d) Six scenarios of DM-only or noDM-only effect sizes are highlighted and respective power estimates are given; these scenarios are marked in the heatmaps by different symbols.

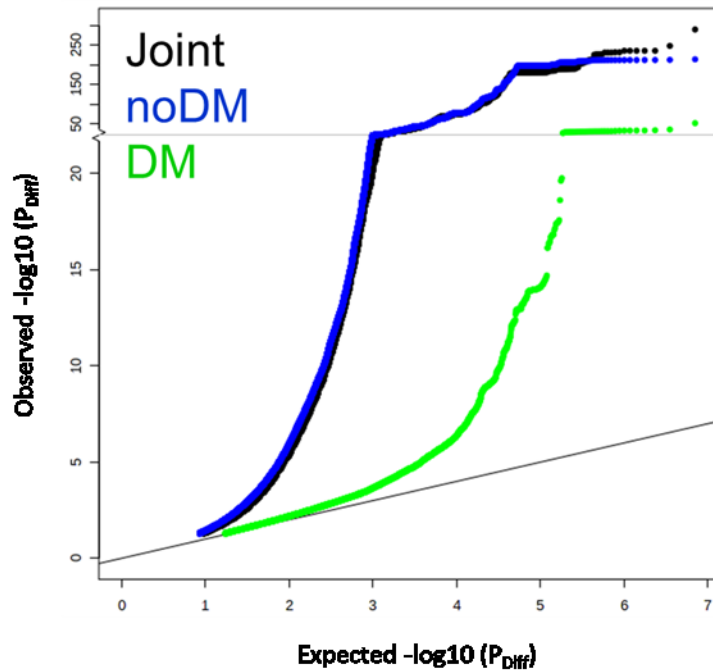

d)

Symbol	Beta		Power			Comment
	DM	noDM	AF = 30%	AF = 5%	AF = 1%	
★	0	0.011	>99%	>99%	19%	Large effect in noDM (~ <i>UMOD/PDILT</i> effect), zero effect in DM
★	0.011	0	>99%	88%	<1%	Large effect in DM (~ <i>UMOD/PDILT</i> effect), zero effect in noDM
●	0	0.004	92%	6%	<1%	Medium effect in noDM, zero effect in DM
●	0.004	0	35%	<1%	<1%	Medium effect in DM, zero effect in noDM
●	0	0.001	<1%	<1%	<1%	Small effect in noDM, zero effect in DM
●	0.001	0	<1%	<1%	<1%	Small effect in DM, zero effect in noDM

Supplementary Figure 7. Distribution of joint, DM-only and noDM-only P-values for eGFR.

Shown are the distributions of observed versus expected P-values (QQ plots) from the joint test (black), noDM-only test (blue) and DM-only test (green) for a) stage 1 ($n_{DM}=109,993$, $n_{noDM}=1,070,999$) and b) combined stage 1+2 ($n_{DM}=178,691$; $n_{noDM}=1,296,113$).

a) Stage 1

b) Stage 1+2

Supplementary Figure 8. Gene prioritisation (GPS) at the seven identified difference loci.

By querying the GPS by Stanzick *et al*², we identified 7 genes located at 6 of the 7 difference loci that were mapping to a credible variant that was deleteriously protein-relevant within the gene (CADD \geq 15⁴), to a credible variant that was an eQTL in kidney tissue^{5,6}, or genes that were known for kidney-related phenotypes in human (OMIM⁷, or Groopman *et al.*¹). For presentation in the main manuscript (**Figure 6**), the list of genes with evidenced kidney phenotype was manually reviewed and reduced.

Supplementary Figure 9. Gene prioritization at the 32 novel eGFR loci yields 22 genes.

By querying the GPS derived for the novel eGFR loci according to the approach described previously² for the 371 genes at the 32 novel loci (**Supplementary Data 11**), we identified 6 genes mapping to a credible variant with PPA>5% that was deleteriously protein-relevant within the gene (CADD ≥ 15 ⁴), 1 gene mapping to a >5% PPA credible variant that was an eQTL in kidney tissue^{5,6}, and 15 genes known for kidney-related phenotypes in human (OMIM⁷, or Groopman et al.¹). For presentation in the main manuscript (**Figure 7**), the list of genes with evidenced kidney phenotype was manually reviewed and reduced.

Locus name	Gene	distance to signal index variant	Chr of gene	Position start of gene	Position end of gene	credible variants in the signal	credible variants in the signal with PPA> 0.05	Score	99% credible variants (PPA > 0.05) within the gene with CADD ≥ 15				99% credible variants (PPA > 0.05) within the locus				Evidenced kidney phenotype for gene	
									stop-gained/ stop-lost/ non-synonymous	canonical-splice/ noncoding-change/ synonymous/ splice-site	other	NEPTUNE glomerulus	NEPTUNE tubulointerstitium	eQTL		sQTL		OMIM Human

Supplementary Note 1. Details on stage 1 overall+difference test approach.

Our stage 1 data (CKDGen and UKB) has been analyzed before for eGFR without DM-/noDM-stratification as described previously ². By this, we yielded 634 independent genome-wide significant variant associations ($P_{\text{Overall}} < 5 \times 10^{-8}$). This was achieved by a step-wise forward selection using approximate conditional analyses: independent variants in a larger region were identified by conditioning on the iteratively identified variants starting by conditioning on the variant with the smallest P-value. Among these 634 variants, 611 variants were analyzable also in DM and noDM, separately. The other 23 variants did not pass quality control filtering thresholds in DM or noDM requiring at least 36 studies in the meta-analysis per stratum. The rs79924715 variant was also excluded because it had already been identified by the difference test approach ($P_{\text{Diff}} < 5 \times 10^{-8}$). The second variant identified by the difference test approach, rs1223328 near *PDE9A*, had a $P_{\text{Overall}} \geq 5 \times 10^{-8}$ and was thus not among the 634 variants. Taken together, we took 610 variants with $P_{\text{Overall}} < 5 \times 10^{-8}$ forward to the difference test.

Among the 610 variants, there were three independent variants in the *UMOD-PDILT* locus besides rs79924715, but only one of these, rs34882080, was significant at $P_{\text{Diff}} < 0.05/610 = 8.2 \times 10^{-5}$, **Supplementary Data 2**). When evaluating the independence of the difference association for rs34882080 by conditioning on rs79924715 via GCTA, we found its difference association to disappear, but the rs7992415 difference association to remain (**Supplementary Figure 2**).

Supplementary Note 2. Robustness of the observed differences.

To investigate the robustness of the seven identified DM/noDM-differential eGFR associations, we performed sensitivity analyses using data from UKB and MVP.

First, we evaluated whether the observed patterns of difference were consistent also when eGFR was analyzed on the original scale instead of log-transformed scale ⁸. When using combined data from UKB and MVP ($n_{\text{DM}}=77,047$, $n_{\text{noDM}}=539,930$) and eGFR without log-transformation, we observed consistent patterns of differences for all identified variants (**Supplementary Table 1**).

Second, we used a SNP-by-DM interaction term in the regression model (instead of the difference test based on DM-stratified effects sizes in the main analysis) based on linear regression and unrelated individuals of European ancestry in UKB ($n_{\text{DM}}=19,277$, $n_{\text{noDM}}=348,728$). We observed significant interaction effects that were directionally consistent with the difference observed by the stratified approach (**Supplementary Data 4**).

Third, interactions with other correlated covariates unaccounted for in the SNP-by-DM interaction analyses are known potential sources of bias in gene-environment interaction studies ⁹. Therefore, we explored extended interaction models using again the unrelated UKB participants of European ancestry ($n_{\text{DM}}=19,277$, $n_{\text{noDM}}=348,728$): the SNP-by-DM interaction

associations were stable also after accounting for SNP-by-Age, SNP-by-Sex, SNP-by-Hypertension or SNP-by-BMI interaction (**Supplementary Data 4**).

In summary, our sensitivity analyses supported the robustness of our observed significant DM/noDM-differential effects at the seven identified loci.

Supplementary Note 3. Power considerations.

We conducted power computations to evaluate the minimum interaction effect size detectable by our combined stage 1+2 data with 180,000 individuals with DM and 1,300,000 individuals with noDM. For this, we considered log-transformed eGFR (age-/sex-adjusted residuals) and a standard deviation as observed in UKB ($sd_{DM}=0.21 \log(\text{ml}/\text{min}/1.73\text{m}^2)$, $sd_{noDM}=0.15 \log(\text{ml}/\text{min}/1.73\text{m}^2)$). We calculated power analytically¹⁰ to identify DM/noDM-difference by the difference approach ($P_{Diff}<5\times 10^{-8}$) or by the overall+difference approach ($P_{Overall}<5\times 10^{-8}$ and $P_{Diff}<0.05/610$, assuming 610 overall associated variants). We considered different effect sizes on log eGFR in DM and noDM based on realistic effects sizes. In UKB, effect sizes on log eGFR overall of the 424 Stanzick *et al*² lead variants ranged from 0.0008 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ (small) to 0.013 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ (large); the *UMOD/PDILT* lead variant showed a large effect size of 0.011 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$. The minor allele frequencies (MAF) of these variants ranged from 1% to 50% with a median of 30%.

We first focused on a common variant (MAF=30%) and calculated power for varying log eGFR effect sizes in DM and noDM (**Supplementary Figure 6a**). For example, assuming a large genetic effect on eGFR of 0.011 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ (comparable to the *UMOD/PDILT* variant), we had >99% power to identify an interaction when the large effect is noDM- or DM-only (**Supplementary Figure 6a,d**). Considering reduced effect sizes of 0.004 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ (medium effect), or 0.001 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ (small effect), the power to identify the interaction was (i) 92% and <1%, respectively for a medium and small noDM-only effect and (ii) 35% and <1%, respectively for a medium and small DM-only effect (**Supplementary Figure 6a,d**). For less frequent variants (MAF<=5%), power was limited (**Supplementary Figure 6b-d**).

The minimum interaction effect size detectable at 80% power for a common variant (MAF=30%) was (i) 0.0037 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ for a noDM-only effect and (ii) 0.0050 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ for a DM-only effect. For low frequency variants (MAF=5%), the minimum detectable effect sizes were (i) 0.0077 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ for a noDM-only effect and (ii) 0.011 $\log(\text{ml}/\text{min}/1.73\text{m}^2)$ for a DM-only effect (**Supplementary Figure 6b,d**).

In summary, the power of the two approaches to detect DM/noDM-differences in genetic effects on eGFR was high for common variants with large noDM-only and DM-only effects as well as for medium noDM-only effects; but limited for medium DM-only effects. For

less frequent or rare variants, realistic DM/noDM-differences in genetic effects on eGFR were not detectable.

Supplementary Note 4. Extended study acknowledgments.

- AA-DHS** NIH R01 DK071891 (Barry I. Freedman, PI); NIH R01 NS075107 (Barry I. Freedman, PI).
- ADVANCE** ADVANCE genomic sub-studies were supported by grants from the Ministry of Science and Innovation from the Quebec Government, from Genome Quebec, from the Consortium Québécois du Médicament, from the Canadian Institutes of Health Research and from Medpharmgene, OPTITHERA Inc and Les Laboratoires Servier.
- AFTER EU** The AFTER EU study is the Danish part of the EURAGEDIC study which was supported by the European Commission (contract QLG2-CT-2001– 01669). The genotyping for this study was part of the Genetics of Diabetic Nephropathy (GenDN) study, primarily funded by Juvenile Diabetes Research Foundation (JDRF) International Prime Award Number 17-2013- 8. Tarunveer S Ahluwalia was also funded by the GenDN study grant and Lundbeck foundation Travel Grant (Ref. Number 2013-14471).
- AGES** This study has been funded by NIA contract N01-AG-12100 and HHSN271201200022C with contributions from NEI, NIDCD and NHLBI, the NIA Intramural Research Program, Hjartavernd (the Icelandic Heart Association), and the Althingi (the Icelandic Parliament). The study is approved by the Icelandic National Bioethics Committee, VSN: 00-063. The researchers thank the participants for their willingness to participate in the study.
- Airwave** We thank all participants in the Airwave Health Monitoring Study. The Airwave Health Monitoring Study is funded by the UK Home Office (780- TETRA; 2003-2018) and the UK Medical Research Council and Economic & Social Research Council (MR/R023484/1; 2018-) with additional support from the National Institute for Health Research (NIHR Imperial College Biomedical Research Centre in collaboration with Imperial College NHS Healthcare Trust. The views expressed are those of the authors and not necessarily those of the sponsors. PE acknowledges support from the Medical Research Council (MR/L01341X/1; MR/S019669/1) for the MRC Centre for Environment and Health. This work used computing resources of the UK MEDical BIOinformatics partnership (UK MED-BIO supported by the Medical Research Council (MR/L01632X/1). PE is supported by the UK Dementia Research

Institute funded by the UK Medical Research Council, Alzheimer's Society and Alzheimer's Research UK (MC_PC_17114) and the Imperial College BritishHeart Foundation Centre for Research Excellence (RE/18/4/34215). PE is associate director of the Health Data Research UK London funded by a consortium led by the UK Medical Research Council.

Amish

We thank the Amish research volunteers for their long-standing partnership in research, and the research staff at the Amish Research Clinic for their work and dedication. The Amish contribution was supported by NIH grants R01 AG18728, R01 HL088119, U01 GM074518, U01 HL072515, U01 HL084756, and NIH K12RR023250, and P30 DK072488. Additional support was provided by the University of Maryland General Clinical Research Center, grant M01 RR 16500, the Baltimore Veterans Administration Medical Center Geriatrics Research, and the Paul Beeson Physician Faculty Scholars in Aging Program.

ARIC

The Atherosclerosis Risk in Communities study has been funded in whole or in part with Federal funds from the National Heart, Lung, and Blood Institute, National Institutes of Health, Department of Health and Human Services (contract numbers HHSN268201700001I, HHSN268201700002I, HHSN268201700003I, HHSN268201700004I and HHSN268201700005I), R01HL087641, R01HL086694; National Human Genome Research Institute contract U01HG004402; and National Institutes of Health contract HHSN268200625226C. The work of AK was funded by the German Research Foundation (DFG) KO 3598/5-1. The authors thank the staff and participants of the ARIC study for their important contributions. Infrastructure was partly supported by Grant Number UL1RR025005, a component of the National Institutes of Health and NIH Roadmap for Medical Research.

ASPS-Fam

The authors thank the staff and participants of the ARIC study for their important contributions. Infrastructure was partly supported by Grant Number UL1RR025005, a component of the National Institutes of Health and NIH Roadmap for Medical Research. The work of Anna Köttgen was supported by a Heisenberg Professorship (KO 3598/3- 1) as well as CRCs 1140 and 992 of the German Research Foundation. The authors thank the staff and the participants for their valuable contributions. We thank Birgit Reinhart for her long-term administrative commitment, Elfi Hofer for the technical assistance at creating the DNA bank, Ing. Johann Semmler and Anita Harb for DNA sequencing and DNA analyses by TaqMan assays and Irmgard Poelzl for supervising the quality management processes after ISO9001 at the

biobanking and DNA analyses. The research reported in this article was funded by the Austrian Science Fond (FWF) grant number P20545-P05, P13180 and PI904 as well as by the Austrian National Bank (OeNB) Anniversary Fund grant number P15435 and the Austrian Federal Ministry of Science, Research and Economy under the aegis of the EU Joint Programme Neurodegenerative Disease Research (JPND)-www.jpnd.eu. The Medical University of Graz supports the databank of the ASPS.

BBJ The BioBank Japan project is supported by the Ministry of Education, Culture, Sports, Sciences and Technology of Japanese government and the Japan Agency for Medical Research and Development. Y.O. was supported by JSPS KAKENHI (19H01021, 20K21834), and AMED (JP21km0405211, JP21ek0109413, JP21ek0410075, JP21gm4010006, and JP21km0405217), JST Moonshot R&D (JPMJMS2021, JPMJMS2024), Takeda Science Foundation.

BES BES was supported by the National Natural Science Foundation of China, (81570835), and the Beijing Municipal of Health Development Project (2019-4).

BioMe The Mount Sinai IPM Biobank Program is supported by The Andrea and Charles Bronfman Philanthropies. Ruth Loos is funded by R01DK110113, U01HG007417, R01DK101855, and R01DK107786.

CHNS The China Health and Nutrition Survey (CHNS) was supported by the China National Institute of Nutrition and Food Safety; the China Center for Disease Control; the National Institutes of Health (R01HD30880, R01HL108427, and R01DK104371); the Fogarty International Center of the National Institutes of Health; the China-Japan Friendship Hospital; the Chinese Ministry of Health; and the Carolina Population Center (R24 HD050924). Cassandra N. Spracklen was supported by the American Heart Association Postdoctoral Fellowship (17POST3650016). Karen Mohlke was supported by R01DK072193 and U01DK105561.

CHRIS CHRIS study investigators thank all study participants, all general practitioners, the personnel of the Hospital of Silandro/Schlanders, and the personnel of the South Tyrolean Healthcare System for their participation and collaboration in the project. Full acknowledgements for the CHRIS study are reported at <https://translational-medicine.biomedcentral.com/articles/10.1186/s12967-015-0704-9>. The CHRIS study was funded by the Department of Innovation, Research, and University of the Autonomous Province of Bolzano/Bozen.

Additional support was provided through R01AG023629 from the National Institute on Aging (NIA). A full list of principal CHS investigators and institutions can be found at CHS-NHLBI.org. The provision of genotyping data was supported in part by the National Center for Advancing Translational Sciences, CTSI grant UL1TR001881, and the National Institute of Diabetes and Digestive and Kidney Disease Diabetes Research Center (DRC) grant DK063491 to the Southern California Diabetes Endocrinology Research Center. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.
- Cilento** We thank the populations of Cilento for their participation in the study. This work was supported by grants from the Italian Ministry of Universities (PON03PE_00060_7, IDF SHARID ARS01_01270), the Assessorato Ricerca Regione Campania.
- CoLaus** The CoLaus|PsyCoLaus study was and is supported by research grants from GlaxoSmithKline, the Faculty of Biology and Medicine of Lausanne, and the Swiss National Science Foundation (grants 3200B0–105993, 3200B0-118308, 33CSCO-122661, 33CS30-139468 and 33CS30-148401).
- CROATIA-Korcula, CROATIA-Split, CROATIA-Vis** 10001 Dalmatians: The Croatian Biobank (CROATIA) The CROATIA-Vis, CROATIA-Korcula and CROATIA-Split were funded by grants from the Medical Research Council (UK), from the Republic of Croatia Ministry of Science, Education and Sports (108-1080315-0302; 216-1080315-0302) and the Croatian Science Foundation (8875); and the CROATIA-Korčula genotyping was funded by the European Union framework program 6 project EUROSPAN (LSHGCT2006018947). We thank the staff of several institutions in Croatia that supported the field work, including Zagreb Medical Schools, the Institute for Anthropological Research in Zagreb, the recruitment team from the Croatian Centre for Global Health, University of Split and all the study participants. We are grateful to the Helmholtz Zentrum Munchen (Munich, Germany), AROS Applied Biotechnology, (Aarhus, Denmark) and

the Edinburgh Clinical Research facility, University of Edinburgh (Edinburgh, United Kingdom) for SNP array genotyping. Genetic analyses were supported by the MRC HGU “QTL in Health and Disease” (MRC University Unit Programme Grant MC_UU_00007/10).

DECODE The study was funded by deCODE Genetics/Amgen inc. We thank the study subjects for their valuable participation and our colleagues, who contributed to data collection, sample handling, and genotyping.

DIACORE Cohort recruiting and management was funded by the KfH Stiftung Präventivmedizin e.V. (Carsten A. Böger). Genome-wide genotyping was funded the Else Kröner-Fresenius-Stiftung (2012_A147), the KfH Stiftung Präventivmedizin and the University Hospital Regensburg. The Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) supported this work – Project-ID 387509280 – SFB 1350 (Subproject C6 to I.M.H.) and Iris Heid and Carsten Böger received funding by DFG BO 3815/4-1.

Diabetic Cohort The Diabetic Cohort (DC) was supported by the individual research grant from the National Medical Research Council (NMRC) and the Biomedical Research Council (BMRC) of Singapore. The Genome Institute of Singapore provided services for genotyping.

EGCUT The EGCUT studies were financed by Estonian Government (grants IUT20-60 and IUT24-6) and by European Commission through the European Regional Development Fund in the frame of grant Estonian Center of Genomics/Roadmap II (project No. 2014-2020.4.01.16-0125) and grant GENTRANSMED (Project No. 2014-2020.4.01.15-0012) and through H2020 grant no 692145 (ePerMed).

This study was supported by the Estonian Research Council grant PRG687. Data analyses were carried out in part in the High-Performance Computing Center of University of Tartu. We thank participants and support staff of Estonian Biobank.

ESTHER The ESTHER study was funded by the Baden-Württemberg state Ministry of Science, Research and Arts (Stuttgart, Germany), the Federal Ministry of Education and Research (Berlin, Germany), and the Federal Ministry of Family Affairs, Senior Citizens, Women and Youth (Berlin, Germany).

FamHS The study was supported by grant R01-DK-089256 from NIDDK and grant R01HL117078 from NHLBI.

FHS The Framingham Heart Study is supported by HHSN268201500001.

FINCAVAS The Finnish Cardiovascular Study (FINCAVAS) has been financially supported by the Competitive Research Funding of the Tampere University

Hospital (Grant 9M048 and 9N035), the Finnish Cultural Foundation, the Finnish Foundation for Cardiovascular Research, the Emil Aaltonen Foundation, Finland, the Tampere Tuberculosis Foundation, EU Horizon 2020 (grant 755320 for TAXINOMISIS and grant 848146 for To Aition), and the Academy of Finland grant 322098. The authors thank the staff of the Department of Clinical Physiology for collecting the exercise test data.

Finrisk

We thank all individuals who participated in Finrisk surveys. Veikko Salomaa, Markus Perola and Mikko Kuokkanen were supported by the Finnish Foundation for Cardiovascular Research. Mikko Kuokkanen was also supported by Päivikki and Sakari Sohlberg Foundation and Yrjö Jahnesson Foundation. We thank the CSC – IT center for science, Finland, for providing computational resources.

GCKD

The GCKD study was funded by the German Ministry of Research and Education (Bundesministerium für Bildung und Forschung, BMBF), by the Foundation KfH Stiftung Präventivmedizin and by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – Projektnummer 246781735 – SFB 1140. Unregistered grants to support the study were provided by Bayer, Fresenius Medical Care and Amgen. Genotyping was supported by Bayer Pharma AG. Uromodulin measurements in GCKD were supported by the Swiss National Centre of Competence in Research Kidney Control of Homeostasis program and the Swiss National Science Foundation grant 31003A_169850. The work of Matthias Wuttke was supported by DFG CRC 1140 and the Else Kroener Fresenius Forschungskolleg NAKSYS. The work of Yong Li was supported by DFG KO 3598/4-1. The work of Anselm Hoppmann was partly supported by NIDDK R01 DK087635-09.

Generation R

The Generation R Study is conducted by the Erasmus Medical Center in close collaboration with the School of Law and Faculty of Social Sciences of the Erasmus University Rotterdam, the Municipal Health Service Rotterdam area, Rotterdam, the Rotterdam Homecare Foundation, Rotterdam and the Stichting Trombosedienst & Artsenlaboratorium Rijnmond (STAR-MDC), Rotterdam. We gratefully acknowledge the contribution of children and parents, general practitioners, hospitals, midwives and pharmacies in Rotterdam. The generation and management of GWAS genotype data for the Generation R Study were done at the Genetic Laboratory of the Department of Internal Medicine, Erasmus MC, The Netherlands. We would like to thank Karol Estrada, Dr. Tobias A. Knoch, Anis Abuseiris, Luc V. de Zeeuw, and

Rob de Graaf, for their help in creating GRIMP, BigGRID, MediGRID, and Services@MediGRID/D-Grid, (funded by the German Bundesministerium fuer Forschung und Technology; grants 01 AK 803 A-H, 01 IG 07015 G) for access to their grid computing resources. We thank Mila Jhamai, Manoushka Ganesh, Pascal Arp, Marijn Verkerk, Lizbeth Herrera and Marjolein Peters for their help in creating, managing and QC of the GWAS database. Also, we thank Karol Estrada for their support in creation and analysis of imputed data. The general design of Generation R Study is made possible by financial support from the Erasmus Medical Center, Rotterdam, the Erasmus University Rotterdam, the Netherlands Organization for Health Research and Development (ZonMw), the Netherlands Organisation for Scientific Research (NWO), the Ministry of Health, Welfare and Sport and the Ministry of Youth and Families. This project received funding from the European Union's Horizon 2020 Research and Innovation Programme under grant agreements 733206 (LifeCycle), 874739 (LongITools) and 824989, (EUCAN-Connect). Fernando Rivadeneira received additional funding from the Netherlands Organization for Health Research and Development (VIDI 016. 136. 367).

GS:SFHS

Generation Scotland received core support from the Chief Scientist Office of the Scottish Government Health Directorates [CZD/16/6] and the Scottish Funding Council [HR03006]. We thank all the families who took part, the general practitioners and the Scottish School of Primary Care for their help in recruiting them, and the whole Generation Scotland team, which includes interviewers, computer and laboratory technicians, clerical workers, research scientists, volunteers, managers, receptionists, healthcare assistants and nurses. Genotyping of the GS:SFHS samples was carried out by the Genetics Core Laboratory at the Edinburgh Clinical Research Facility, University of Edinburgh, Scotland and was funded by the Medical Research Council UK and the Wellcome Trust (Wellcome Trust Strategic Award "STratifying Resilience and Depression Longitudinally" (STRADL) Reference 104036/Z/14/Z).

GSK

Funding Source: Max-Planck Society, German Federal Ministry of Education and Research (BMBF) in the framework of the National Genome Research Network (NGFN), Foerderkennzeichen 01GS0481.

HANDLS

The authors thank Dr. Salman M. Tajuddin, all study participants and the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study medical staff for their contributions. The HANDLS study was supported

by the Intramural Research Program of the NIH, National Institute on Aging and the National Center on Minority Health and Health Disparities (project # Z01-AG000513 and human subjects protocol number 09-AG-N248). Data analyses for the HANDLS study utilized the high-performance computational resources of the Biowulf Linux cluster at the National Institutes of Health, Bethesda, MD. (<http://biowulf.nih.gov>; <http://hpc.nih.gov>).

HUNT

The Trøndelag Health Study (The HUNT Study) is a collaboration between HUNT Research Centre (Faculty of Medicine and Health Sciences, NTNU, Norwegian University of Science and Technology), Trøndelag County Council, Central Norway Regional Health Authority, and the Norwegian Institute of Public Health. The HUNT study was approved by the Central Norway Regional Committee for Medical and Health Research Ethics (REC Central no. 2015/1188), and written informed consent was given by all participants.

HYPERGENE S

Funding Source: HYPERGENES project (FP7-HEALTH-F4-2007-201550) and InterOmics (PB05 MIUR-CNR Italian Flagship Project).

INGI-CARL

The project was approved by the local administration of Carlantino, the Health Service of Foggia Province, Italy, and ethical committee of the IRCCS Burlo-Garofolo of Trieste. We thank the people of Carlantino for their support.

INGI-FVG

Project co-financed by the European Regional Development Fund under the Regional Operational Programme of Friuli Venezia Giulia - Objective "Regional Competitiveness and Employment" 2007/2013, Telethon Foundation (GGP09037), Fondo Trieste (2008), Regione FVG (L.26.2008), and Italian Ministry of Health (RC16/06, ART. 13 D.LGS 297/99) (to Paolo Gasparini). We thank the people of Friuli Venezia Giulia Region for their support.

INGI-VBI

The research was supported by funds from Compagnia di San Paolo, Torino, Italy; Fondazione Cariplo, Italy and Ministry of Health, Ricerca Finalizzata 2011 and CCM 2010 to Daniela Toniolo. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript. We thank the inhabitants of the VB that made this study possible, the local administrations, the Tortona and Genova archdiocese and the ASL-22, Novi Ligure (AI) for support. We thank Clara Camaschella for data collection supervision and organization of the clinical data collection, Fiammetta Viganò for technical help, and Corrado Masciullo for the analysis platform.

- JHS** The Jackson Heart Study (JHS) is supported and conducted in collaboration with Jackson State University (HHSN268201800013I), Tougaloo College (HHSN268201800014I), the Mississippi State Department of Health (HHSN268201800015I/HHSN26800001) and the University of Mississippi Medical Center (HHSN268201800010I, HHSN268201800011I and HHSN268201800012I) contracts from the National Heart, Lung, and Blood Institute (NHLBI) and the National Institute for Minority Health and Health Disparities (NIMHD). The authors also wish to thank the staffs and participants of the JHS. Laura M. Raffield is supported by T32 HL129982.
- JUPITER** The JUPITER trial and its genetic substudy were funded by AstraZeneca.
- KORA** The KORA research platform (KORA, Cooperative Health Research in the Region of Augsburg) was initiated and financed by the Helmholtz Zentrum München - German Research Center for Environmental Health, which is funded by the German Federal Ministry of Education and Research and by the State of Bavaria. Furthermore, KORA research was supported within the Munich Center of Health Sciences (MC Health), Ludwig-Maximilians Universität, as part of LMUinnovativ. Statistical KORA analyses were supported by DFG BO-3815/4-1 (to Carsten A. Böger), BMBF 01ER1206, 01ER1507 (to Iris M. Heid), by the University of Regensburg and by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – Project-ID 387509280 – SFB 1350 (Subproject C6 to I.M.H.) and DFG BO 3815/4-1.
- LIFE-Adult, LIFE-Heart, LIFE-Child** LIFE-Adult, LIFE-Heart, and LIFE-Child, are funded by the Leipzig Research Center for Civilization Diseases (LIFE). LIFE is an organizational unit affiliated to the Medical Faculty of the University of Leipzig. LIFE is funded by means of the European Union, by the European Regional Development Fund (ERDF) and by funds of the Free State of Saxony within the framework of the excellence initiative.
- Lifelines** The LifeLines Cohort Study, and generation and management of GWAS genotype data for the LifeLines Cohort Study is supported by the UMCG Genetics Lifelines Initiative (UGLI), the Netherlands Organization of Scientific Research NWO (grant 175.010.2007.006), the Economic Structure Enhancing Fund (FES) of the Dutch government, the Ministry of Economic Affairs, the Ministry of Education, Culture and Science, the Ministry for Health, Welfare and Sports, the Northern Netherlands Collaboration of Provinces (SNN), the Province of Groningen, University Medical Center Groningen, the University of Groningen, Dutch Kidney Foundation and Dutch Diabetes Research

Foundation. The authors wish to acknowledge the services of the Lifelines Cohort Study, the contributing research centers delivering data to Lifelines, and all the study participants.

Living-Biobank

The genotyping was funded by the Agency for Science, Technology and Research, Singapore (<https://www.a-star.edu.sg/>), and by Merck Sharp & Dohme Corp., Whitehouse Station, NJ USA (<http://www.merck.com>). The participants were from the MEC study (funded by the Biomedical Research Council (BMRC 03/1/27/18/216), National Medical Research Council (0838/2004), National Research Foundation (through BMRC 05/1/21/19/425 and 11/1/21/19/678), Ministry of Health, Singapore, National University of Singapore and National University Health System, Singapore), and The SH2012 study (funded by the Ministry of Health, Singapore, National University of Singapore and National University Health System, Singapore).

LLFS

The study was supported by grants: U01AG023746, U01AG023712, U01AG023749, U01AG023755, U01AG023744, and U19AG063893 from NIA.

LOLIPOP

The LOLIPOP study is supported by the National Institute for Health Research (NIHR) Comprehensive Biomedical Research Centre Imperial College Healthcare NHS Trust, the British Heart Foundation (SP/04/002), the Medical Research Council (G0601966, G0700931), the Wellcome Trust (084723/Z/08/Z, 090532 & 098381) the NIHR (RP-PG-0407-10371), the NIHR Official Development Assistance (ODA, award 16/136/68), the European Union FP7 (EpiMigrant, 279143), and H2020 programs (iHealthT2D, 643774). We acknowledge support of the MRC-PHE Centre for Environment and Health, and the NIHR Health Protection Research Unit on Health Impact of Environmental Hazards. The work was carried out in part at the NIHR/Wellcome Trust Imperial Clinical Research Facility. The views expressed are those of the author(s) and not necessarily those of the Imperial College Healthcare NHS Trust, the NHS, the NIHR or the Department of Health. We thank the participants and research staff who made the study possible. JC is supported by the Singapore Ministry of Health's National Medical Research Council under its Singapore Translational Research Investigator (STaR) Award (NMRC/STaR/0028/2017).

LURIC

LURIC was supported by the 7th Framework Program of the EU (AtheroRemo, grant agreement number 201668 and RiskyCAD, grant agreement number 305739). The work of G.E.D. is supported by the European Union's Horizon 2020 research and innovation programme under

the ERA-Net Cofund action N° 727565 (OCTOPUS project) and the German Ministry of Education and Research (grant number 01EA1801A). The authors thank the LURIC study team involved in patient recruitment as well as sample and data handling, and the laboratory staff at the Ludwigshafen General Hospital and the universities of Freiburg, Ulm and Heidelberg, Germany.

MDC-CC

This study was supported by the European Research Council (Consolidator grant nr 649021, Orho-Melander), the Swedish Research Council, the Swedish Heart and Lung Foundation, the Novo Nordic Foundation, the Swedish Diabetes Foundation, and the Pålsson Foundation, and by equipment grants from the Knut and Alice Wallenberg Foundation, the Region Skåne, Skåne University Hospital, the Linneus Foundation for the Lund University Diabetes Center and Swedish Foundation for Strategic Research for IRC15-0067.

MESA

MESA and the MESA SHARe projects are conducted and supported by the National Heart, Lung, and Blood Institute (NHLBI) in collaboration with MESA investigators. Support for MESA is provided by contracts 75N92020D00001, HHSN[268201500003](#), N01-HC-95159, 75N92020D00005, N01-HC-95160, 75N92020D00002, N01-HC-95161, 75N92020D00003, N01-HC-95162, 75N92020D00006, N01-HC-95163, 75N92020D00004, N01-HC-95164, 75N92020D00007, N01-HC-95165, N01-HC-95166, N01-HC-95167, N01-HC-95168, N01-HC-95169, UL1-TR-000040, UL1-TR-001079, UL1-TR-001420. Funding for SHARe genotyping was provided by NHLBI Contract N02-HL-64278. Genotyping was performed at Affymetrix (Santa Clara, California, USA) and the Broad Institute of Harvard and MIT (Boston, Massachusetts, USA) using the Affymetrix Genome-Wide Human SNP Array 6.0. MESA Family is conducted and supported by the National Heart, Lung, and Blood Institute (NHLBI) in collaboration with MESA investigators. Support is provided by grants and contracts R01HL071051, R01HL071205, R01HL071250, R01HL071251, R01HL071258, R01HL071259, by the National Center for Research Resources, Grant UL1RR033176. This publication was developed under Science to Achieve Results (STAR) research assistance agreements, No. RD[831697](#) (MESA Air), and RD-[83830001](#) (MESA Air Next Stage), awarded by the U.S Environmental protection Agency. It has not been formally reviewed by the EPA. The views expressed in this document are solely those of the authors and the EPA does not endorse any products or commercial services mentioned in this publication. The provision of genotyping data was supported in part by the

National Center for Advancing Translational Sciences, CTSI grant UL1TR001881, and the National Institute of Diabetes and Digestive and Kidney Disease Diabetes Research Center (DRC) grant DK063491 to the Southern California Diabetes Endocrinology Research Center. Infrastructure for the CHARGE Consortium is supported in part by the National Heart, Lung, and Blood Institute (NHLBI) grant R01HL105756.

METSIM Michael Boehnke was supported by NIH grant DK062370. Markku Laakso was supported by the Academy of Finland (grant no. 321428) and the Sigrid Juselius Foundation.

MGI The authors acknowledge the Michigan Genomics Initiative participants, Precision Health at the University of Michigan, the University of Michigan Medical School Central Biorepository, and the University of Michigan Advanced Genomics Core for providing data and specimen storage, management, processing, and distribution services, and the Center for Statistical Genetics in the Department of Biostatistics at the School of Public Health for genotype data curation, imputation, and management in support of the research reported in this publication.

MICROS MICROS study investigators thank all study participants, all primary care practitioners, and the personnel of the Hospital of Silandro/Schlanders, and the personnel of the South Tyrolean Health System for their participation and collaboration in the project.. The study was supported by the Ministry of Health and Department of Educational Assistance, University and Research of the Autonomous Province of Bolzano, the South Tyrolean Sparkasse Foundation, and the European Union framework program 6 EUROSPAN project (contract no. LSHG-CT- 2006-018947).

MyCode (Geisinger) We would like to acknowledge the participants, staff, and our colleagues associated with the Geisinger MyCode Community Health Initiative. We also thank the staff of the PACDC of Geisinger for assistance with the phenotypic data, and the staff of the Biomedical & Translational Informatics and Kidney Health Research Institute.

MVP The work on MVP was funded by the Veterans Health Administration Clinical Science & Research MeritCX00189. “Genetics of CKD and Hypertension-Risk Prediction and Drug Response” in the MVP to Adriana M. Hung.

NEO The authors of the NEO study thank all individuals who participated in the Netherlands Epidemiology in Obesity study, all participating general practitioners for inviting eligible participants and all research nurses for collection of the data. We thank the NEO study group, Pat van Beelen, Petra

Noordijk and Ingeborg de Jonge for the coordination, lab and data management of the NEO study. The genotyping in the NEO study was supported by the Centre National de Génotypage (Paris, France), headed by Jean-Francois Deleuze. The NEO study is supported by the participating Departments, the Division and the Board of Directors of the Leiden University Medical Center, and by the Leiden University, Research Profile Area Vascular and Regenerative Medicine. Dennis Mook-Kanamori is supported by Dutch Science Organization (ZonMW-VENI Grant 916.14.023).

NESDA For NESDA, funding was obtained from the Netherlands Organization for Scientific Research (Geestkracht program grant 10-000-1002); the Center for Medical Systems Biology (CSMB, NWO Genomics), Biobanking and Biomolecular Resources Research Infrastructure (BBMRI-NL), VU University's Institutes for Health and Care Research (EMGO+) and Neuroscience Campus Amsterdam, University Medical Center Groningen, Leiden University Medical Center, National Institutes of Health (NIH, R01D0042157-01A, MH081802, Grand Opportunity grants 1RC2 MH089951 and 1RC2 MH089995). Part of the genotyping and analyses were funded by the Genetic Association Information Network (GAIN) of the Foundation for the National Institutes of Health. Computing was supported by BiG Grid, the Dutch e-Science Grid, which is financially supported by NWO.

OGP The Ogliastra Genetic Park study was supported by grant from the Italian Ministry of Education, University and Research (MIUR) no. 5571/DSPAR/2002. We thank all study participants for their contributions and the municipal administrations for their economic and logistic support.

ORCADES The Orkney Complex Disease Study (ORCADES) was supported by the Chief Scientist Office of the Scottish Government (CZB/4/276, CZB/4/710), a Royal Society URF to James F. Wilson, the MRC Human Genetics Unit quinquennial programme "QTL in Health and Disease", Arthritis Research UK and the European Union framework program 6 EUROSPAN project (contract no. LSHG-CT-2006-018947). DNA extractions were performed at the Wellcome Trust Clinical Research Facility in Edinburgh. We would like to acknowledge the invaluable contributions of the research nurses in Orkney, the administrative team in Edinburgh, the people of Orkney, and the data analysts in particular Dr Thibaud Boutin for the genotype imputation to the HRC reference panel.

PIVUS Prospective Investigation of the Vasculature in Uppsala Seniors (**PIVUS**) was supported by Wellcome Trust Grants (WT098017, WT064890, WT090532),

Uppsala University, Uppsala University Hospital, the Swedish Research Council and the Swedish Heart-Lung Foundation.

PREVEND The Prevention of Renal and Vascular Endstage Disease Study (PREVEND) genetics is supported by the Dutch Kidney Foundation (Grant E033), the EU project grant GENECURE (FP-6 LSHM CT 2006 037697), the National Institutes of Health (grant LM010098), the Netherlands organization for health research and development (NWO VENI grant 916.761.70), and the Dutch Inter University Cardiology Institute Netherlands (ICIN). Niek Verweij was supported by NWO VENI grant 016.186.125.

POPGEN The PopGen 2.0 network was supported by a grant from the German Ministry for Education and Research (01EY1103). AF and WL receive funding from the DFG Excellence Cluster “Precision Medicine in Chronic Inflammation” (PMI; EXC 2167)

QIMR adolescent We acknowledge funding by Australian National Health and Medical Research Council (NHMRC) grants 241944, 339462, 389927, 389875, 389891, 389892, 389938, 442915, 442981, 496739, 552485, 552498 and Australian Research Council grants A7960034, A79906588, A79801419, DP0770096, DP0212016, DP0343921 for building and maintaining the adolescent twin family resource through which samples were collected.

RS The Rotterdam Study (RS) has been approved by the Medical Ethics Committee of the Erasmus MC (registration number MEC 02.1015) and by the Dutch Ministry of Health, Welfare and Sport (Population Screening Act WBO, license number 1071272-159521-PG). The RS has been entered into the Netherlands National Trial Register (NTR; www.trialregister.nl) and into the WHO International Clinical Trials Registry Platform (ICTRP; www.who.int/ictip/network/primary/en/) under shared catalogue number NTR6831. All participants provided written informed consent to participate in the study and to have their information obtained from treating physicians. The generation and management of GWAS genotype data for the RS (RS I, RS II, RS III) was executed by the Human Genotyping Facility of the Genetic Laboratory of the Department of Internal Medicine, Erasmus MC, Rotterdam, The Netherlands. The GWAS datasets are supported by the Netherlands Organisation of Scientific Research NWO Investments (nr. 175.010.2005.011, 911-03-012), the Genetic Laboratory of the Department of Internal Medicine, Erasmus MC, the Research Institute for Diseases in the Elderly (014-93-015; RIDE2), the Netherlands Genomics Initiative (NGI)/Netherlands Organisation for Scientific Research (NWO) Netherlands Consortium for Healthy Aging

(NCHA), project nr. 050-060- 810. We thank Pascal Arp, Mila Jhamai, Marijn Verkerk, Lizbeth Herrera and Marjolein Peters, MSc, and Carolina Medina-Gomez, MSc, for their help in creating the GWAS database, and Karol Estrada, PhD, Yurii Aulchenko, PhD, and Carolina Medina-Gomez, MSc, for the creation and analysis of imputed data. The RS is funded by Erasmus Medical Center and Erasmus University, Rotterdam, Netherlands Organization for the Health Research and Development (ZonMw), the Research Institute for Diseases in the Elderly (RIDE), the Ministry of Education, Culture and Science, the Ministry for Health, Welfare and Sports, the European Commission (DG XII), and the Municipality of Rotterdam. The authors are grateful to the study participants, the staff from the RS and the participating general practitioners and pharmacists.

- SCES** The Singapore Chinese Eye Study (SCES) was supported by grants from the National Medical Research Council (STaR/0003/2008), the Singapore Bio Imaging Consortium (C-011/2006) and the Biomedical Research Council (08/1/35/19/550). The Genome Institute of Singapore provided services for genotyping.
- SCHS - CHD cases and controls** The Singapore Chinese Health Study was supported by the National Institutes of Health, USA (RO1 CA144034 and UM1 CA182876), the nested case-control study of myocardial infarction by the Singapore National Medical Research Council (NMRC 1270/2010), and genotyping by the HUU-CREATE Programme of the National Research Foundation, Singapore (Project Number 370062002).
- SHIP/SHIP-Trend** SHIP is part of the Community Medicine Research net of the University of Greifswald, Germany, which is funded by the Federal Ministry of Education and Research (grants no. 01ZZ9603, 01ZZ0103, and 01ZZ0403), the Ministry of Cultural Affairs as well as the Social Ministry of the Federal State of Mecklenburg-West Pomerania, and the network 'Greifswald Approach to Individualized Medicine (GANI_MED)' funded by the Federal Ministry of Education and Research (grant 03IS2061A). Genome-wide data have been supported by the Federal Ministry of Education and Research (grant no. 03ZIK012) and a joint grant from Siemens Healthineers, Erlangen, Germany and the Federal State of Mecklenburg- West Pomerania. The University of Greifswald is a member of the Caché Campus program of the InterSystems GmbH.
- SiMES** The Singapore Malay Eye Study (SiMES) was funded by the National Medical Research Council (NMRC 0796/2003 and NMRC/STaR/0003/2008) and

Biomedical Research Council (BMRC, 09/1/35/19/616). The Genome Institute of Singapore provided services for genotyping.

SINDI The Singapore Indian Eye Study (SINDI) was funded by grants from the Biomedical Research Council of Singapore (BMRC 09/1/35/19/616 and 08/1/35/19/550), and the National Medical Research Council of Singapore (NMRC/STaR/0003/2008). The Genome Institute of Singapore provided services for genotyping.

SKIPOGH The SKIPOGH study was supported by a Swiss national science foundation grant (FN33CM30-124087 and FN33CM30-140331), by the Swiss National Centres of Competence in Research Kidney and TransCure. Olivier Devuyst was supported by Swiss National Science Foundation (project grant 31003A-169850) and the Swiss National Centre of Competence in Research (NCCR) Kidney Control of Homeostasis (Kidney.CH).

SOLID-TIMI 52 The SOLID-TIMI 52 trial was supported and funded by grants from GlaxoSmithKline.

Sorbs This work was supported by grants from the German Research Foundation (SFB-1052 "Obesity mechanisms" A01, B03, SPP 1629 TO 718/2- 1), from the German Diabetes Association, from the DHFD (Diabetes Hilfs- und Forschungsfonds Deutschland) and from IFB Adiposity Diseases (AD2- 060E, AD2-06E95, AD2-06E99). IFB Adiposity Diseases is supported by the Federal Ministry of Education and Research (BMBF), Germany, FKZ:01EO1501.

SP2 The Singapore Prospective Study Program (SP2) were supported by the individual research grant and clinician scientist award schemes from the National Medical Research Council (NMRC) and the Biomedical Research Council (BMRC) of Singapore. The Genome Institute of Singapore provided services for genotyping.

STABILITY The STABILITY trial was supported and funded by grants from GlaxoSmithKline.

TRAILS TRAILS (TRacking Adolescents' Individual Lives Survey) is a collaborative project involving various departments of the University Medical Center and University of Groningen, the University of Utrecht, the Radboud Medical Center Nijmegen, and the Parnassia Group, all in the Netherlands. TRAILS has been financially supported by various grants from the Netherlands Organization for Scientific Research NWO (Medical Research Council program grant GB-MW 940-38-011; ZonMW Brainpower grant 100-001-004; ZonMw Risk Behavior and Dependence grants 60-60600-97-118; ZonMw

Culture and Health grant 261-98-710; Social Sciences Council medium-sized investment grants GB-MaGW 480-01-006 and GB-MaGW 480-07-001; Social Sciences Council project grants GB-MaGW 452-04-314 and GB-MaGW 452-06-004; NWO large-sized investment grant 175.010.2003.005; NWO Longitudinal Survey and Panel Funding 481-08-013 and 481-11-001; NWO Vici 016.130.002 and 453-16-007/2735; NWO Gravitation 024.001.003), the Dutch Ministry of Justice (WODC), the European Science Foundation (EuroSTRESS project FP-006), the European Research Council (ERC-2017-STG-757364 en ERC-CoG-2015-681466), Biobanking and Biomolecular Resources Research Infrastructure BBMRI-NL (CP 32), the Gratama foundation, the Jan Dekker foundation, the participating universities, and Accare Centre for Child and Adolescent Psychiatry. Statistical analyses were carried out on the Genetic Cluster Computer (<http://www.geneticcluster.org>), which is financially supported by the Netherlands Scientific Organization (NWO 480-05-003) along with a supplement from the Dutch Brain Foundation. We are grateful to everyone who participated in this research or worked on this project to make it possible.

TwinGene

TwinGene is a sub-study of the Swedish Twin Registry which is managed by Karolinska Institutet and receives funding through the Swedish Research Council under the grant no 2017-00641. TwinGene was supported by grants from the Swedish Research Council (M-2005-1112), GenomEUtwin (EU/QLRT-2001-01254; QLG2-CT-2002-01254), NIH DK U01-066134, The Swedish Foundation for Strategic Research (SSF). Heart and Lung foundation no. 20070481. Analysis on renal biomarkers was supported by grants from Stockholm County Council, The Swedish Society of Medicine (SLS-412071), the Serafimer Hospital Foundation, Stiftelsen för Njursjuka and The Swedish Kidney Foundation (F2019-0003).

ULSAM

The ULSAM study was supported by Wellcome Trust grants WT098017, WT064890, WT090532, Uppsala University, Uppsala University Hospital, the Swedish Research Council and the Swedish Heart-Lung Foundation. Johan Ärnlöv was supported by The Swedish Research Council, Swedish Heart-Lung Foundation, Dalarna University and Uppsala University.

Vanderbilt

The data used for the analyses were obtained from Vanderbilt University Medical Center's BioVU, which is supported by numerous sources: institutional funding, private agencies, and federal grants. These include the

NIH funded Shared Instrumentation Grant S10RR025141; and CTSA grants UL1TR002243, UL1TR000445, and UL1RR024975. Genomic data are also supported by investigator-led projects that include U01HG004798, R01NS032830, RC2GM092618, P50GM115305, U01HG006378, U19HL065962, R01HD074711; and additional funding sources listed at <https://victr.vanderbilt.edu/pub/biovu/>. Jacklyn N. Hellwege is supported by the Vanderbilt Molecular and Genetic Epidemiology of Cancer training program, funded by T32CA160056.

VIKING

The Viking Health Study – Shetland (VIKING) was supported by the MRC Human Genetics Unit quinquennial programme grant “QTL in Health and Disease”. DNA extractions and genotyping were performed at the Edinburgh Clinical Research Facility, University of Edinburgh. We acknowledge the contributions of the research nurses in Shetland, the administrative team in Edinburgh, the people of Shetland, and the data analysts, in particular Dr Thibaud Boutin for the genotype imputation to the HRC reference panel.

WGHS

The Women's Genome Health Study (WGHS) is supported by the National Heart, Lung, and Blood Institute (HL043851 and HL080467) and the National Cancer Institute (CA047988 and UM1CA182913) with funding for genotyping provided by Amgen.

YFS

The Young Finns Study has been financially supported by the Academy of Finland: grants 322098, 286284, 134309 (Eye), 126925, 121584, 124282, 129378 (Salve), 117787 (Gendi), and 41071 (Skidi); the Social Insurance Institution of Finland; Competitive State Research Financing of the Expert Responsibility area of Kuopio, Tampere and Turku University Hospitals (grant X51001); Juho Vainio Foundation; Paavo Nurmi Foundation; Finnish Foundation for Cardiovascular Research ; Finnish Cultural Foundation; The Sigrid Juselius Foundation; Tampere Tuberculosis Foundation; Emil Aaltonen Foundation; Yrjö Jahnsson Foundation; Signe and Ane Gyllenberg Foundation; Diabetes Research Foundation of Finnish Diabetes Association; EU Horizon 2020 (grant 755320 for TAXINOMISIS and grant 848146 for To Aition); European Research Council (grant 742927 for MULTIEPIGEN project); Tampere University Hospital Supporting Foundation and Finnish Society of Clinical Chemistry. We thank the teams that collected data at all measurement time points; the persons who participated as both children and adults in these longitudinal studies; and biostatisticians Irina Lisinen, Johanna Ikonen, Noora Kartiosuo, Ville Aalto, and Jarno Kankaanranta for data management and statistical advice.

Supplementary Note 5. VA Million Veteran Program: Core Acknowledgement for Publications (Updated April 6, 2020).

MVP Executive Committee

- Co-Chair: J. Michael Gaziano, M.D., M.P.H.
- Co-Chair: Sumitra Muralidhar, Ph.D.
- Rachel Ramoni, D.M.D., Sc.D., Chief VA Research and Development Officer
- Jean Beckham, Ph.D.
- Kyong-Mi Chang, M.D.
- Christopher J. O'Donnell, M.D., M.P.H.
- Philip S. Tsao, Ph.D.
- James Breeling, M.D., Ex-Officio
- Grant Huang, Ph.D., Ex-Officio
- JP Casas Romero, M.D., Ph.D., Ex-Officio

- Jennifer Moser, Ph.D.

MVP Recruitment/Enrollment

- Recruitment/Enrollment Director/Deputy Director, Boston – Stacey B. Whitbourne, Ph.D.; Jessica V. Brewer, M.P.H.
- MVP Coordinating Centers
 - o Clinical Epidemiology Research Center (CERC), West Haven – Mihaela Aslan, Ph.D.
 - o Cooperative Studies Program Clinical Research Pharmacy Coordinating Center, Albuquerque – Todd Connor, Pharm.D.; Dean P. Argyres, B.S., M.S.
 - o Genomics Coordinating Center, Palo Alto – Philip S. Tsao, Ph.D.
 - o MVP Boston Coordinating Center, Boston - J. Michael Gaziano, M.D., M.P.H.
 - o MVP Information Center, Canandaigua – Brady Stephens, M.S.
- VA Central Biorepository, Boston – Mary T. Brophy M.D., M.P.H.; Donald E. Humphries, Ph.D. Luis E. Selva, Ph.D.
- MVP Informatics, Boston – Nhan Do, M.D.; Shahpoor Shayan
- MVP Data Operations/Analytics, Boston – Kelly Cho, Ph.D.

MVP Science

- Science Operations – Christopher J. O'Donnell, M.D., M.P.H
- Genomics Core - Christopher J. O'Donnell, M.D., M.P.H.; Saiju Pyarajan Ph.D.; Philip S. Tsao, Ph.D.
- Phenomics Core- Kelly Cho, M.P.H, Ph.D.
- Data and Computational Sciences – Saiju Pyarajan, Ph.D.
- Statistical Genetics – Elizabeth Hauser, Ph.D.; Yan Sun, Ph.D.; Hongyu Zhao, Ph.D.

Current MVP Local Site Investigators

- Atlanta VA Medical Center (Peter Wilson, M.D.)
- Bay Pines VA Healthcare System (Rachel McArdle, Ph.D.)

- Birmingham VA Medical Center (Louis Dellitalia, M.D.)
- Central Western Massachusetts Healthcare System (Kristin Mattocks, Ph.D., M.P.H.)
- Cincinnati VA Medical Center (John Harley, M.D., Ph.D.)
- Clement J. Zablocki VA Medical Center (Jeffrey Whittle, M.D., M.P.H.)
- VA Northeast Ohio Healthcare System (Frank Jacono, M.D.)
- Durham VA Medical Center (Jean Beckham, Ph.D.)
- Edith Nourse Rogers Memorial Veterans Hospital (John Wells., Ph.D.)
- Edward Hines, Jr. VA Medical Center (Salvador Gutierrez, M.D.)
- Veterans Health Care System of the Ozarks (Gretchen Gibson, D.D.S., M.P.H.)
- Fargo VA Health Care System (Kimberly Hammer, Ph.D.)
- VA Health Care Upstate New York (Laurence Kaminsky, Ph.D.)
- New Mexico VA Health Care System (Gerardo Villareal, M.D.)
- VA Boston Healthcare System (Scott Kinlay, M.B.B.S., Ph.D.)
- VA Western New York Healthcare System (Junzhe Xu, M.D.)
- Ralph H. Johnson VA Medical Center (Mark Hamner, M.D.)
- Columbia VA Health Care System (Roy Mathew, M.D.)
- VA North Texas Health Care System (Sujata Bhushan, M.D.)
- Hampton VA Medical Center (Pran Iruvanti, D.O., Ph.D.)
- Richmond VA Medical Center (Michael Godschalk, M.D.)
- Iowa City VA Health Care System (Zuhair Ballas, M.D.)
- Eastern Oklahoma VA Health Care System (Douglas Ivins, M.D.)
- James A. Haley Veterans' Hospital (Stephen Mastorides, M.D.)
- James H. Quillen VA Medical Center (Jonathan Moorman, M.D., Ph.D.)
- John D. Dingell VA Medical Center (Saib Gappy, M.D.)
- Louisville VA Medical Center (Jon Klein, M.D., Ph.D.)
- Manchester VA Medical Center (Nora Ratcliffe, M.D.)
- Miami VA Health Care System (Hermes Florez, M.D., Ph.D.)
- Michael E. DeBakey VA Medical Center (Olaoluwa Okusaga, M.D.)
- Minneapolis VA Health Care System (Maureen Murdoch, M.D., M.P.H.)
- N. FL/S. GA Veterans Health System (Peruvemba Sriram, M.D.)
- Northport VA Medical Center (Shing Shing Yeh, Ph.D., M.D.)
- Overton Brooks VA Medical Center (Neeraj Tandon, M.D.)
- Philadelphia VA Medical Center (Darshana Jhala, M.D.)
- Phoenix VA Health Care System (Samuel Aguayo, M.D.)
- Portland VA Medical Center (David Cohen, M.D.)
- Providence VA Medical Center (Satish Sharma, M.D.)
- Richard Roudebush VA Medical Center (Suthat Liangpunsakul, M.D., M.P.H.)
- Salem VA Medical Center (Kris Ann Oursler, M.D.)
- San Francisco VA Health Care System (Mary Whooley, M.D.)
- South Texas Veterans Health Care System (Sunil Ahuja, M.D.)
- Southeast Louisiana Veterans Health Care System (Joseph Constans, Ph.D.)
- Southern Arizona VA Health Care System (Paul Meyer, M.D., Ph.D.)
- Sioux Falls VA Health Care System (Jennifer Greco, M.D.)
- St. Louis VA Health Care System (Michael Rauchman, M.D.)
- Syracuse VA Medical Center (Richard Servatius, Ph.D.)
- VA Eastern Kansas Health Care System (Melinda Gaddy, Ph.D.)
- VA Greater Los Angeles Health Care System (Agnes Wallbom, M.D., M.S.)
- VA Long Beach Healthcare System (Timothy Morgan, M.D.)

- VA Maine Healthcare System (Todd Stapley, D.O.)
- VA New York Harbor Healthcare System (Scott Sherman, M.D., M.P.H.)
- VA Pacific Islands Health Care System (George Ross, M.D.)
- VA Palo Alto Health Care System (Philip Tsao, Ph.D.)
- VA Pittsburgh Health Care System (Patrick Stollo, Jr., M.D.)
- VA Puget Sound Health Care System (Edward Boyko, M.D.)
- VA Salt Lake City Health Care System (Laurence Meyer, M.D., Ph.D.)
- VA San Diego Healthcare System (Samir Gupta, M.D., M.S.C.S.)
- VA Sierra Nevada Health Care System (Mostaqul Huq, Pharm.D., Ph.D.)
- VA Southern Nevada Healthcare System (Joseph Fayad, M.D.)
- VA Tennessee Valley Healthcare System (Adriana Hung, M.D., M.P.H.)
- Washington DC VA Medical Center (Jack Lichy, M.D., Ph.D.)
- W.G. (Bill) Hefner VA Medical Center (Robin Hurley, M.D.)
- White River Junction VA Medical Center (Brooks Robey, M.D.)
- William S. Middleton Memorial Veterans Hospital (Robert Striker, M.D., Ph.D.)

Supplementary Note 6. LifeLines group author genetics.
